2.1 Primitive logic

The definition of the logic is based on Mike Gordon's technical report [2] that describes the first implementation of HOL. However, there are a number of differences. In particular, we start with the definite description operator and introduce Hilbert's ε operator only much later. Moreover, axiom $(P \longrightarrow Q) \longrightarrow (Q \longrightarrow P) \longrightarrow (P = Q)$ is derived from the other axioms. The fact that this axiom is derivable was first noticed by Bruno Barras (for Mike Gordon's line of HOL systems) and later independently by Alexander Maletzky (for Isabelle/HOL).

2.1.1 Core syntax

```
setup ‹Axclass.class-axiomatization (binding ‹type›, [])›
default-sort type
setup ‹Object-Logic.add-base-sort sort ‹type››

setup ‹Proofterm.set-preproc (Proof-Rewrite-Rules.standard-preproc [])›

axiomatization where fun-arity: OFCLASS('a ⇒ 'b, type-class)
instance fun :: (type, type) type by (rule fun-arity)

axiomatization where itself-arity: OFCLASS('a itself, type-class)
instance itself :: (type) type by (rule itself-arity)

typedecl bool

judgment Trueprop :: bool ⇒ prop  (‹(‹notation=judgment›-)› 5)

axiomatization implies :: [bool, bool] ⇒ bool  (infixr ‹⟶› 25)
  and eq :: ['a, 'a] ⇒ bool
  and The :: ('a ⇒ bool) ⇒ 'a

notation (input)
```

eq (**infixl** ‹=› *50*)
notation (**output**)
eq (**infix** ‹=› *50*)

The input syntax for *eq* is more permissive than the output syntax because of the large amount of material that relies on infixl.

2.1.2 Defined connectives and quantifiers

definition *True* :: *bool*
where *True* ≡ ((λ*x*::*bool*. *x*) = (λ*x*. *x*))

definition *All* :: (*'a* ⇒ *bool*) ⇒ *bool* (**binder** ‹∀› *10*)
where *All P* ≡ (*P* = (λ*x*. *True*))

definition *Ex* :: (*'a* ⇒ *bool*) ⇒ *bool* (**binder** ‹∃› *10*)
where *Ex P* ≡ ∀ *Q*. (∀ *x*. *P x* ⟶ *Q*) ⟶ *Q*

definition *False* :: *bool*
where *False* ≡ (∀ *P*. *P*)

definition *Not* :: *bool* ⇒ *bool* (‹(‹*open-block notation*=‹*prefix* ¬››¬ -)› [*40*] *40*)
where *not-def*: ¬ *P* ≡ *P* ⟶ *False*

definition *conj* :: [*bool*, *bool*] ⇒ *bool* (**infixr** ‹∧› *35*)
where *and-def*: *P* ∧ *Q* ≡ ∀ *R*. (*P* ⟶ *Q* ⟶ *R*) ⟶ *R*

definition *disj* :: [*bool*, *bool*] ⇒ *bool* (**infixr** ‹∨› *30*)
where *or-def*: *P* ∨ *Q* ≡ ∀ *R*. (*P* ⟶ *R*) ⟶ (*Q* ⟶ *R*) ⟶ *R*

definition *Uniq* :: (*'a* ⇒ *bool*) ⇒ *bool*
where *Uniq P* ≡ (∀ *x y*. *P x* ⟶ *P y* ⟶ *y* = *x*)

definition *Ex1* :: (*'a* ⇒ *bool*) ⇒ *bool*
where *Ex1 P* ≡ ∃ *x*. *P x* ∧ (∀ *y*. *P y* ⟶ *y* = *x*)

2.1.3 Additional concrete syntax

2.1.4 Axioms and basic definitions

axiomatization where
  refl: t = (t::'a) **and**
  subst: s = t ⟹ P s ⟹ P t **and**
  ext: (⋀x::'a. (f x ::'b) = g x) ⟹ (λx. f x) = (λx. g x)
  — Extensionality is built into the meta-logic, and this rule expresses a related property. It is an eta-expanded version of the traditional rule, and similar to the ABS rule of HOL **and**

  the-eq-trivial: (THE x. x = a) = (a::'a)

axiomatization where
  impI: (P ⟹ Q) ⟹ P ⟶ Q **and**
  mp: ⟦P ⟶ Q; P⟧ ⟹ Q **and**

  True-or-False: (P = True) ∨ (P = False)

definition *If* :: *bool* ⇒ *'a* ⇒ *'a* ⇒ *'a* (‹(‹*notation*=‹*mixfix if expression*››*if* (-)/ *then* (-)/ *else* (-))› [*0*, *0*, *10*] *10*)
  where *If P x y* ≡ (*THE z*::*'a*. (*P* = *True* ⟶ *z* = *x*) ∧ (*P* = *False* ⟶ *z* = *y*))

definition *Let* :: *'a* ⇒ (*'a* ⇒ *'b*) ⇒ *'b*
  where *Let s f* ≡ *f s*

nonterminal *letbinds* **and** *letbind*

open-bundle *let-syntax*
begin

syntax
  -bind :: [*pttrn*, *'a*] ⇒ *letbind* (‹(‹*indent*=*2* *notation*=‹*mixfix let binding*››- =/ -)› *10*)
  :: *letbind* ⇒ *letbinds* (‹-›)
  -binds :: [*letbind*, *letbinds*] ⇒ *letbinds* (‹-;/ -›)
  -Let :: [*letbinds*, *'a*] ⇒ *'a* (‹(‹*notation*=‹*mixfix let expression*››*let* (-)/ *in* (-))› [*0*, *10*] *10*)
syntax-consts
  -bind -binds -Let ⇌ *Let*
translations
  -Let (*-binds b bs*) *e* ⇌ *-Let b* (*-Let bs e*)
  let x = *a in e* ⇌ *CONST Let a* (λ*x*. *e*)

end

axiomatization *undefined* :: *'a*

class *default* = **fixes** *default* :: *'a*

2.2 Fundamental rules

2.2.1 Equality

lemma *sym*: *s* = *t* ⟹ *t* = *s*
  by (*erule subst*) (*rule refl*)

lemma *ssubst*: *t* = *s* ⟹ *P s* ⟹ *P t*
  by (*drule sym*) (*erule subst*)

lemma *trans*: ⟦*r* = *s*; *s* = *t*⟧ ⟹ *r* = *t*
  by (*erule subst*)

lemma *trans-sym* [*Pure.elim?*]: *r* = *s* ⟹ *t* = *s* ⟹ *r* = *t*
  by (*rule trans* [*OF* - *sym*])

lemma *meta-eq-to-obj-eq*:
  assumes *A* ≡ *B*
  shows *A* = *B*

unfolding *assms* **by** (*rule refl*)

Useful with *erule* for proving equalities from known equalities.

lemma *box-equals*: $\llbracket a = b;\ a = c;\ b = d \rrbracket \Longrightarrow c = d$
by (*iprover intro*: *sym trans*)

For calculational reasoning:

lemma *forw-subst*: $a = b \Longrightarrow P\ b \Longrightarrow P\ a$
by (*rule ssubst*)

lemma *back-subst*: $P\ a \Longrightarrow a = b \Longrightarrow P\ b$
by (*rule subst*)

2.2.2 Congruence rules for application

Similar to *AP-THM* in Gordon's HOL.

lemma *fun-cong*: $(f :: 'a \Rightarrow 'b) = g \Longrightarrow f\ x = g\ x$
by (*iprover intro*: *refl elim*: *subst*)

Similar to *AP-TERM* in Gordon's HOL and FOL's *subst-context*.

lemma *arg-cong*: $x = y \Longrightarrow f\ x = f\ y$
by (*iprover intro*: *refl elim*: *subst*)

lemma *arg-cong2*: $\llbracket a = b;\ c = d \rrbracket \Longrightarrow f\ a\ c = f\ b\ d$
by (*iprover intro*: *refl elim*: *subst*)

lemma *cong*: $\llbracket f = g;\ (x{::}'a) = y \rrbracket \Longrightarrow f\ x = g\ y$
by (*iprover intro*: *refl elim*: *subst*)

ML ‹*fun cong-tac ctxt* = *Cong-Tac.cong-tac ctxt* @{*thm cong*}›

2.2.3 Equality of booleans – iff

lemma *iffD2*: $\llbracket P = Q;\ Q \rrbracket \Longrightarrow P$
by (*erule ssubst*)

lemma *rev-iffD2*: $\llbracket Q;\ P = Q \rrbracket \Longrightarrow P$
by (*erule iffD2*)

lemma *iffD1*: $Q = P \Longrightarrow Q \Longrightarrow P$
by (*drule sym*) (*rule iffD2*)

lemma *rev-iffD1*: $Q \Longrightarrow Q = P \Longrightarrow P$
by (*drule sym*) (*rule rev-iffD2*)

lemma *iffE*:
assumes *major*: $P = Q$
and *minor*: $\llbracket P \longrightarrow Q;\ Q \longrightarrow P \rrbracket \Longrightarrow R$

shows *R*
by (*iprover intro*: *minor impI major* [*THEN iffD2*] *major* [*THEN iffD1*])

2.2.4 True (1)

lemma *TrueI*: *True*
unfolding *True-def* **by** (*rule refl*)

lemma *eqTrueE*: $P = True \Longrightarrow P$
by (*erule iffD2*) (*rule TrueI*)

2.2.5 Universal quantifier (1)

lemma *spec*: $\forall x::'a.\ P\ x \Longrightarrow P\ x$
unfolding *All-def* **by** (*iprover intro*: *eqTrueE fun-cong*)

lemma *allE*:
assumes *major*: $\forall x.\ P\ x$ **and** *minor*: $P\ x \Longrightarrow R$
shows *R*
by (*iprover intro*: *minor major* [*THEN spec*])

lemma *all-dupE*:
assumes *major*: $\forall x.\ P\ x$ **and** *minor*: $[\![P\ x; \forall x.\ P\ x]\!] \Longrightarrow R$
shows *R*
by (*iprover intro*: *minor major major* [*THEN spec*])

2.2.6 False

Depends upon *spec*; it is impossible to do propositional logic before quantifiers!

lemma *FalseE*: $False \Longrightarrow P$
unfolding *False-def* **by** (*erule spec*)

lemma *False-neq-True*: $False = True \Longrightarrow P$
by (*erule eqTrueE* [*THEN FalseE*])

2.2.7 Negation

lemma *notI*:
assumes $P \Longrightarrow False$
shows $\neg\ P$
unfolding *not-def* **by** (*iprover intro*: *impI assms*)

lemma *False-not-True*: $False \neq True$
by (*iprover intro*: *notI elim*: *False-neq-True*)

lemma *True-not-False*: $True \neq False$
by (*iprover intro*: *notI dest*: *sym elim*: *False-neq-True*)

lemma *notE*: $[\![\neg\ P;\ P]\!] \Longrightarrow R$
  unfolding *not-def*
  by (*iprover intro*: *mp* [*THEN FalseE*])

2.2.8 Implication

lemma *impE*:
  assumes $P \longrightarrow Q$ P $Q \Longrightarrow R$
  shows R
  by (*iprover intro*: *assms mp*)

Reduces Q to $P \longrightarrow Q$, allowing substitution in P.

lemma *rev-mp*: $[\![P;\ P \longrightarrow Q]\!] \Longrightarrow Q$
  by (*rule mp*)

lemma *contrapos-nn*:
  assumes *major*: $\neg\ Q$
    and *minor*: $P \Longrightarrow Q$
  shows $\neg\ P$
  by (*iprover intro*: *notI minor major* [*THEN notE*])

Not used at all, but we already have the other 3 combinations.

lemma *contrapos-pn*:
  assumes *major*: Q
    and *minor*: $P \Longrightarrow \neg\ Q$
  shows $\neg\ P$
  by (*iprover intro*: *notI minor major notE*)

lemma *not-sym*: $t \neq s \Longrightarrow s \neq t$
  by (*erule contrapos-nn*) (*erule sym*)

lemma *eq-neq-eq-imp-neq*: $[\![x = a;\ a \neq b;\ b = y]\!] \Longrightarrow x \neq y$
  by (*erule subst*, *erule ssubst*, *assumption*)

2.2.9 Disjunction (1)

lemma *disjE*:
  assumes *major*: $P \vee Q$
    and *minorP*: $P \Longrightarrow R$
    and *minorQ*: $Q \Longrightarrow R$
  shows R
  by (*iprover intro*: *minorP minorQ impI*
      major [*unfolded or-def*, *THEN spec*, *THEN mp*, *THEN mp*])

2.2.10 Derivation of *iffI*

In an intuitionistic version of HOL *iffI* needs to be an axiom.

lemma *iffI*:
  assumes $P \Longrightarrow Q$ **and** $Q \Longrightarrow P$

```
  shows P = Q
proof (rule disjE[OF True-or-False[of P]])
  assume 1: P = True
  note Q = assms(1)[OF eqTrueE[OF this]]
  from 1 show ?thesis
  proof (rule ssubst)
    from True-or-False[of Q] show True = Q
    proof (rule disjE)
      assume Q = True
      thus ?thesis by(rule sym)
    next
      assume Q = False
      with Q have False by (rule rev-iffD1)
      thus ?thesis by (rule FalseE)
    qed
  qed
next
  assume 2: P = False
  thus ?thesis
  proof (rule ssubst)
    from True-or-False[of Q] show False = Q
    proof (rule disjE)
      assume Q = True
      from 2 assms(2)[OF eqTrueE[OF this]] have False by (rule iffD1)
      thus ?thesis by (rule FalseE)
    next
      assume Q = False
      thus ?thesis by(rule sym)
    qed
  qed
qed
```

2.2.11 True (2)

```
lemma eqTrueI: P ⟹ P = True
  by (iprover intro: iffI TrueI)
```

2.2.12 Universal quantifier (2)

```
lemma allI:
  assumes ⋀x::'a. P x
  shows ∀x. P x
  unfolding All-def by (iprover intro: ext eqTrueI assms)
```

2.2.13 Existential quantifier

```
lemma exI: P x ⟹ ∃x::'a. P x
  unfolding Ex-def by (iprover intro: allI allE impI mp)

lemma exE:
```

assumes *major*: $\exists x{::}'a.\ P\ x$
and *minor*: $\bigwedge x.\ P\ x \Longrightarrow Q$
shows Q
by (*rule major* [*unfolded Ex-def*, *THEN spec*, *THEN mp*]) (*iprover intro*: *impI* [*THEN allI*] *minor*)

2.2.14 Conjunction

lemma *conjI*: $[\![P;\ Q]\!] \Longrightarrow P \wedge Q$
unfolding *and-def* **by** (*iprover intro*: *impI* [*THEN allI*] *mp*)

lemma *conjunct1*: $[\![P \wedge Q]\!] \Longrightarrow P$
unfolding *and-def* **by** (*iprover intro*: *impI dest*: *spec mp*)

lemma *conjunct2*: $[\![P \wedge Q]\!] \Longrightarrow Q$
unfolding *and-def* **by** (*iprover intro*: *impI dest*: *spec mp*)

lemma *conjE*:
assumes *major*: $P \wedge Q$
and *minor*: $[\![P;\ Q]\!] \Longrightarrow R$
shows R
proof (*rule minor*)
show P **by** (*rule major* [*THEN conjunct1*])
show Q **by** (*rule major* [*THEN conjunct2*])
qed

lemma *context-conjI*:
assumes $P\ P \Longrightarrow Q$
shows $P \wedge Q$
by (*iprover intro*: *conjI assms*)

2.2.15 Disjunction (2)

lemma *disjI1*: $P \Longrightarrow P \vee Q$
unfolding *or-def* **by** (*iprover intro*: *allI impI mp*)

lemma *disjI2*: $Q \Longrightarrow P \vee Q$
unfolding *or-def* **by** (*iprover intro*: *allI impI mp*)

2.2.16 Classical logic

lemma *classical*:
assumes $\neg\ P \Longrightarrow P$
shows P
proof (*rule True-or-False* [*THEN disjE*])
show P **if** $P = \mathit{True}$
using *that* **by** (*iprover intro*: *eqTrueE*)
show P **if** $P = \mathit{False}$
proof (*intro notI assms*)
assume P

with *that* **show** *False*
by (*iprover elim*: *subst*)
qed
qed

lemmas *ccontr* = *FalseE* [*THEN classical*]

notE with premises exchanged; it discharges $\neg R$ so that it can be used to make elimination rules.

lemma *rev-notE*:
assumes *premp*: P
and *premnot*: $\neg R \Longrightarrow \neg P$
shows R
by (*iprover intro*: *ccontr notE* [*OF premnot premp*])

Double negation law.

lemma *notnotD*: $\neg\neg P \Longrightarrow P$
by (*iprover intro*: *ccontr notE*)

lemma *contrapos-pp*:
assumes *p1*: Q
and *p2*: $\neg P \Longrightarrow \neg Q$
shows P
by (*iprover intro*: *classical p1 p2 notE*)

2.2.17 Unique existence

lemma *Uniq-I* [*intro?*]:
assumes $\bigwedge x\ y.\ [\![P\ x;\ P\ y]\!] \Longrightarrow y = x$
shows *Uniq P*
unfolding *Uniq-def* **by** (*iprover intro*: *assms allI impI*)

lemma *Uniq-D* [*dest?*]: $[\![\mathit{Uniq}\ P;\ P\ a;\ P\ b]\!] \Longrightarrow a{=}b$
unfolding *Uniq-def* **by** (*iprover dest*: *spec mp*)

lemma *ex1I*:
assumes $P\ a\ \bigwedge x.\ P\ x \Longrightarrow x = a$
shows $\exists!x.\ P\ x$
unfolding *Ex1-def* **by** (*iprover intro*: *assms exI conjI allI impI*)

Sometimes easier to use: the premises have no shared variables. Safe!

lemma *ex-ex1I*:
assumes *ex-prem*: $\exists x.\ P\ x$
and *eq*: $\bigwedge x\ y.\ [\![P\ x;\ P\ y]\!] \Longrightarrow x = y$
shows $\exists!x.\ P\ x$
by (*iprover intro*: *ex-prem* [*THEN exE*] *ex1I eq*)

lemma *ex1E*:
assumes *major*: $\exists!x.\ P\ x$ **and** *minor*: $\bigwedge x.\ [\![P\ x;\ \forall y.\ P\ y \longrightarrow y = x]\!] \Longrightarrow R$

shows R
proof (*rule major* [*unfolded Ex1-def*, *THEN exE*])
show $\bigwedge x.\ P\ x \wedge (\forall\, y.\ P\ y \longrightarrow y = x) \Longrightarrow R$
by (*iprover intro*: *minor elim*: *conjE*)
qed

by (*iprover intro*: *exI elim*: *ex1E*)

2.2.18 Classical intro rules for disjunction and existential quantifiers

lemma *disjCI*:
assumes $\neg\ Q \Longrightarrow P$
shows $P \vee Q$
by (*rule classical*) (*iprover intro*: *assms disjI1 disjI2 notI elim*: *notE*)

lemma *excluded-middle*: $\neg\ P \vee P$
by (*iprover intro*: *disjCI*)

case distinction as a natural deduction rule. Note that $\neg\ P$ is the second case, not the first.

lemma *case-split* [*case-names True False*]:
assumes $P \Longrightarrow Q\ \neg\ P \Longrightarrow Q$
shows Q
using *excluded-middle* [*of P*]
by (*iprover intro*: *assms elim*: *disjE*)

Classical implies ($\longrightarrow$) elimination.

lemma *impCE*:
assumes *major*: $P \longrightarrow Q$
and *minor*: $\neg\ P \Longrightarrow R\ Q \Longrightarrow R$
shows R
using *excluded-middle* [*of P*]
by (*iprover intro*: *minor major* [*THEN mp*] *elim*: *disjE*)+

This version of $\longrightarrow$ elimination works on Q before P. It works best for those cases in which P holds "almost everywhere". Can't install as default: would break old proofs.

lemma *impCE'*:
assumes *major*: $P \longrightarrow Q$
and *minor*: $Q \Longrightarrow R\ \neg\ P \Longrightarrow R$
shows R
using *assms* **by** (*elim impCE*)

The analogous introduction rule for conjunction, above, is even constructive

lemma *context-disjE*:
assumes *major*: $P \vee Q$ **and** *minor*: $P \Longrightarrow R\ \neg P \Longrightarrow Q \Longrightarrow R$

shows R
by (*iprover intro*: *disjE* [*OF major*] *disjE* [*OF excluded-middle*] *assms*)

Classical $\longleftrightarrow$ elimination.

lemma *iffCE*:
assumes *major*: $P = Q$
and *minor*: $[\![P;\ Q]\!] \Longrightarrow R$ $[\![\neg\ P;\ \neg\ Q]\!] \Longrightarrow R$
shows R
by (*rule major* [*THEN iffE*]) (*iprover intro*: *minor elim*: *impCE notE*)

ML ‹*val HOL-ss = simpset-of* ***context***›

Simplifies x assuming c and y assuming $\neg\ c$.

lemma *if-cong*:
assumes $b = c$
and $c \Longrightarrow x = u$
and $\neg\ c \Longrightarrow y = v$

shows $(\textit{if } b \textit{ then } x \textit{ else } y) = (\textit{if } c \textit{ then } u \textit{ else } v)$
using *assms* **by** *simp*

Prevents simplification of x and y: faster and allows the execution of functional programs.

lemma *if-weak-cong* [*cong*]:
assumes $b = c$
shows $(\textit{if } b \textit{ then } x \textit{ else } y) = (\textit{if } c \textit{ then } x \textit{ else } y)$
using *assms* **by** (*rule arg-cong*)

Prevents simplification of t: much faster

lemma *let-weak-cong*:
assumes $a = b$
shows $(\textit{let } x = a \textit{ in } t\ x) = (\textit{let } x = b \textit{ in } t\ x)$
using *assms* **by** (*rule arg-cong*)

To tidy up the result of a simproc. Only the RHS will be simplified.

lemma *eq-cong2*:
assumes $u = u'$
shows $(t \equiv u) \equiv (t \equiv u')$
using *assms* **by** *simp*

lemma *if-distrib*: $f\ (\textit{if } c \textit{ then } x \textit{ else } y) = (\textit{if } c \textit{ then } f\ x \textit{ else } f\ y)$
by *simp*

lemma *if-distribR*: $(\textit{if } b \textit{ then } f \textit{ else } g)\ x = (\textit{if } b \textit{ then } f\ x \textit{ else } g\ x)$
by *simp*

lemma *all-if-distrib*: $(\forall x.\ \textit{if } x = a \textit{ then } P\ x \textit{ else } Q\ x) \longleftrightarrow P\ a \wedge (\forall x.\ x \neq a \longrightarrow Q\ x)$
by *auto*

lemma *ex-if-distrib*: $(\exists x.\ \textit{if } x = a \textit{ then } P\ x \textit{ else } Q\ x) \longleftrightarrow P\ a \vee (\exists x.\ x \neq a \wedge Q\ x)$
by *auto*

lemma *if-if-eq-conj*: $(\textit{if } P \textit{ then if } Q \textit{ then } x \textit{ else } y \textit{ else } y) = (\textit{if } P \wedge Q \textit{ then } x \textit{ else } y)$
by *simp*

As a simplification rule, it replaces all function equalities by first-order equalities.

lemma *fun-eq-iff*: $f = g \longleftrightarrow (\forall x.\ f\ x = g\ x)$
by *auto*

3 *NO-MATCH* simproc

The simplification procedure can be used to avoid simplification of terms of a certain form.

definition *NO-MATCH* :: $'a \Rightarrow 'b \Rightarrow bool$
  where *NO-MATCH pat val* $\equiv$ *True*

lemma *NO-MATCH-cong*[*cong*]: *NO-MATCH pat val* = *NO-MATCH pat val*
  by (*rule refl*)

declare [[*coercion-args NO-MATCH* $-$ $-$]]

simproc-setup *NO-MATCH* (*NO-MATCH pat val*) = ‹*K* (*fn ctxt* => *fn ct* =>
let
val thy = *Proof-Context.theory-of ctxt*
val dest-binop = *Term.dest-comb* #> *apfst* (*Term.dest-comb* #> *snd*)
val m = *Pattern.matches thy* (*dest-binop* (*Thm.term-of ct*))
in if m then NONE else SOME @{*thm NO-MATCH-def*} *end*)
›

This setup ensures that a rewrite rule of the form *NO-MATCH pat val* $\Longrightarrow$ *t* is only applied, if the pattern *pat* does not match the value *val*.

Tagging a premise of a simp rule with ASSUMPTION forces the simplifier not to simplify the argument and to solve it by an assumption.

definition *ASSUMPTION* :: *bool* $\Rightarrow$ *bool*
where *ASSUMPTION A* $\equiv$ *A*

method-setup order = ‹
  Scan.succeed (fn ctxt => SIMPLE-METHOD' (HOL-Order-Tac.tac [] ctxt))
› partial and linear order reasoner
```

The method *order* allows one to use the order tactic located in `../Provers/order_tac.ML` in a standalone fashion.

The tactic rearranges the goal to prove *False*, then retrieves order literals of partial and linear orders (i.e. $x = y$, $x \leq y$, $x < y$, and their negated versions) from the premises and finally tries to derive a contradiction. Its main use case is as a solver to *simp* (see below), where it e.g. solves premises of conditional rewrite rules.

The tactic has two configuration attributes that control its behaviour:

- *order-trace* toggles tracing for the solver.
- *order-split-limit* limits the number of order literals of the form $\neg\ x < y$ that are passed to the tactic. This is helpful since these literals lead to case splitting and thus exponential runtime. This only applies to partial orders.

  We setup the solver for HOL with the structure `HOL_Order_Tac` here but the prover is agnostic to the object logic. It is possible to register orders with the prover using the functions `HOL_Order_Tac.declare_order` and `HOL_Order_Tac.declare_linorder`, which we do below for the type classes *order* and *linorder*. If possible, one should instantiate these type classes instead of registering new orders with the solver. One can also interpret the type class locales *order* and *linorder*. An example can be seen in `Library/Sublist.thy`, which contains e.g. the prefix order on lists.

The diagnostic command **print-orders** shows all orders known to the tactic in the current context.

Declarations to set up transitivity reasoner of partial and linear orders.

5.1 Dynamic facts

named-theorems *ac-simps associativity and commutativity simplification rules*
and *algebra-simps algebra simplification rules for rings*
and *algebra-split-simps algebra simplification rules for rings*, *with potential goal splitting*
and *field-simps algebra simplification rules for fields*
and *field-split-simps algebra simplification rules for fields*, *with potential goal splitting*

The rewrites accumulated in *algebra-simps* deal with the classical algebraic structures of groups, rings and family. They simplify terms by multiplying everything out (in case of a ring) and bringing sums and products into a canonical form (by ordered rewriting). As a result it decides group and ring equalities but also helps with inequalities.

Of course it also works for fields, but it knows nothing about multiplicative inverses or division. This is catered for by *field-simps*.

Facts in *field-simps* multiply with denominators in (in)equations if they can be proved to be non-zero (for equations) or positive/negative (for inequalities). Can be too aggressive and is therefore separate from the more benign *algebra-simps*.

Collections *algebra-split-simps* and *field-split-simps* correspond to *algebra-simps* and *field-simps* but contain more aggresive rules that may lead to goal splitting.

5.2 Abstract structures

These locales provide basic structures for interpretation into bigger structures; extensions require careful thinking, otherwise undesired effects may occur due to interpretation.

qed

The rule *split-paired-all* does not work with the Simplifier because it also affects premises in congrence rules, where this can lead to premises of the form $\bigwedge$*a b*. ... = *?P*(*a*, *b*) which cannot be solved by reflexivity.

lemmas *split-tupled-all* = *split-paired-all unit-all-eq2*

Class *normalization-semidom* cultivates the idea that each integral domain can be split into equivalence classes whose representants are associated, i.e. divide each other. *normalize* specifies a canonical representant for each equivalence class. The rationale behind this is that it is easier to reason about equality than equivalences, hence we prefer to think about equality of normalized values rather than associated elements.

We avoid an explicit definition of associated elements but prefer explicit normalisation instead. In theory we could define an abbreviation like *associated a b* = (*normalize a* = *normalize b*) but this is counterproductive without suggestive infix syntax, which we do not want to sacrifice for this purpose here.

16.7 Ordered semirings and rings

The theory of partially ordered rings is taken from the books:

- *Lattice Theory* by Garret Birkhoff, American Mathematical Society, 1979
- *Partially Ordered Algebraic Systems*, Pergamon Press, 1963

Most of the used notions can also be looked up in

- http://www.mathworld.com by Eric Weisstein et. al.
- *Algebra I* by van der Waerden, Springer

20.5 A basic fold functional for finite sets

The intended behaviour is *fold* f z $\{x_1, \ldots, x_n\} = f\ x_1\ (\ldots\ (f\ x_n\ z)\ldots)$ if f is "left-commutative". The commutativity requirement is relativised to the carrier set S:

locale *comp-fun-commute-on* =
fixes S :: $'a$ *set*
fixes f :: $'a \Rightarrow 'b \Rightarrow 'b$
assumes *comp-fun-commute-on*: $x \in S \Longrightarrow y \in S \Longrightarrow f\ y \circ f\ x = f\ x \circ f\ y$
begin

lemma *fun-left-comm*: $x \in S \Longrightarrow y \in S \Longrightarrow f\ y\ (f\ x\ z) = f\ x\ (f\ y\ z)$
using *comp-fun-commute-on* **by** (*simp add*: *fun-eq-iff*)

lemma *commute-left-comp*: $x \in S \Longrightarrow y \in S \Longrightarrow f\ y \circ (f\ x \circ g) = f\ x \circ (f\ y \circ g)$
by (*simp add*: *o-assoc comp-fun-commute-on*)

end

inductive *fold-graph* :: $('a \Rightarrow 'b \Rightarrow 'b) \Rightarrow 'b \Rightarrow 'a\ set \Rightarrow 'b \Rightarrow bool$
for f :: $'a \Rightarrow 'b \Rightarrow 'b$ **and** z :: $'b$
where
emptyI [*intro*]: *fold-graph* f z $\{\}$ z

21 Reflexive and Transitive closure of a relation

theory *Transitive-Closure*
  imports *Finite-Set*
  abbrevs ^* = * **
    and ^+ = $^+$ $^{++}$
    and ^= = $^=$ $^{==}$

begin

ML-file ‹~~/src/Provers/trancl.ML›

rtrancl is reflexive/transitive closure, *trancl* is transitive closure, *reflcl* is reflexive closure.

These postfix operators have *maximum priority*, forcing their operands to be atomic.

context notes [[*inductive-internals*]]

Intuition: We find an $R \cup S$-min element of a nonempty subset A by case distinction.

1. There is a step $a\ {-R\rightarrow}\ b$ with $a,\ b \in A$. Pick an R-min element z of the (nonempty) set $\{a{\in}A \mid \exists b{\in}A.\ a\ {-R\rightarrow}\ b\}$. By definition, there is $z' \in A$ s.t. $z\ {-R\rightarrow}\ z'$. Because z is R-min in the subset, z' must be R-min in A. Because z' has an R-predecessor, it cannot have an S-successor and is thus S-min in A as well.

2. There is no such step. Pick an S-min element of A. In this case it must be an R-min element of A as well.

24.5.2 The upper and lower bounds operators

Here we define upper ("above") and lower ("below") bounds operators. We think of r as a *non-strict* relation. The suffix S at the names of some operators indicates that the bounds are strict – e.g., *underS a* is the set of all strict lower bounds of a (w.r.t. r). Capitalization of the first letter in the name reminds that the operator acts on sets, rather than on individual elements.

definition *under* :: $'a\ rel \Rightarrow 'a \Rightarrow 'a\ set$
  where $under\ r\ a \equiv \{b.\ (b, a) \in r\}$

definition *underS* :: $'a\ rel \Rightarrow 'a \Rightarrow 'a\ set$
  where $underS\ r\ a \equiv \{b.\ b \neq a \wedge (b, a) \in r\}$

definition *Under* :: $'a\ rel \Rightarrow 'a\ set \Rightarrow 'a\ set$
where $Under\ r\ A \equiv \{b \in Field\ r.\ \forall a \in A.\ (b,\ a) \in r\}$

definition *UnderS* :: $'a\ rel \Rightarrow 'a\ set \Rightarrow 'a\ set$
where $UnderS\ r\ A \equiv \{b \in Field\ r.\ \forall a \in A.\ b \neq a \wedge (b,\ a) \in r\}$

definition *above* :: $'a\ rel \Rightarrow 'a \Rightarrow 'a\ set$
where $above\ r\ a \equiv \{b.\ (a,\ b) \in r\}$

definition *aboveS* :: $'a\ rel \Rightarrow 'a \Rightarrow 'a\ set$
where $aboveS\ r\ a \equiv \{b.\ b \neq a \wedge (a,\ b) \in r\}$

definition *Above* :: $'a\ rel \Rightarrow 'a\ set \Rightarrow 'a\ set$
where $Above\ r\ A \equiv \{b \in Field\ r.\ \forall a \in A.\ (a,\ b) \in r\}$

definition *AboveS* :: $'a\ rel \Rightarrow 'a\ set \Rightarrow 'a\ set$
where $AboveS\ r\ A \equiv \{b \in Field\ r.\ \forall a \in A.\ b \neq a \wedge (a,\ b) \in r\}$

definition *ofilter* :: $'a\ rel \Rightarrow 'a\ set \Rightarrow bool$
where $ofilter\ r\ A \equiv A \subseteq Field\ r \wedge (\forall a \in A.\ under\ r\ a \subseteq A)$

Note: In the definitions of *Above*[*S*] and *Under*[*S*], we bounded comprehension by *Field r* in order to properly cover the case of *A* being empty.

24.6 Variations on Well-Founded Relations

This subsection contains some variations of the results from *HOL.Wellfounded*:

- means for slightly more direct definitions by well-founded recursion;
- variations of well-founded induction;
- means for proving a linear order to be a well-order.

24.6.1 Characterizations of well-foundedness

A transitive relation is well-founded iff it is "locally" well-founded, i.e., iff its restriction to the lower bounds of of any element is well-founded.

lemma *trans-wf-iff*:
  assumes *trans r*
  shows $wf\ r \longleftrightarrow (\forall a.\ wf\ (r \cap (r^{-1} `` \{a\} \times r^{-1} `` \{a\})))$
proof −
  define R **where** $R\ a = r \cap (r^{-1} `` \{a\} \times r^{-1} `` \{a\})$ **for** a
  have $wf\ (R\ a)$ **if** $wf\ r$ **for** a
    using *that R-def wf-subset*[*of r R a*] **by** *auto*
  moreover
  have $wf\ r$ **if** $*$: $\forall a.\ wf(R\ a)$

Every infinite set contains a countable subset. More precisely we show that a set S is infinite if and only if there exists an injective function from the naturals into S.

The "only if" direction is harder because it requires the construction of a sequence of pairwise different elements of an infinite set S. The idea is to construct a sequence of non-empty and infinite subsets of S obtained by successively removing elements of S.

26 Zorn's Lemma and the Well-ordering Theorem

```
theory Zorn
  imports Order-Relation Hilbert-Choice
begin
```

26.1 Zorn's Lemma for the Subset Relation

26.1.1 Results that do not require an order

Let P be a binary predicate on the set A.

```
locale pred-on =
  fixes A :: 'a set
   and P :: 'a ⇒ 'a ⇒ bool (infix ‹⊏› 50)
begin

abbreviation Peq :: 'a ⇒ 'a ⇒ bool (infix ‹⊑› 50)
  where x ⊑ y ≡ P== x y
```

A chain is a totally ordered subset of A.

```
definition chain :: 'a set ⇒ bool
  where chain C ⟷ C ⊆ A ∧ (∀x∈C. ∀y∈C. x ⊑ y ∨ y ⊑ x)
```

We call a chain that is a proper superset of some set X, but not necessarily a chain itself, a superchain of X.

abbreviation *superchain* :: $'a\ set \Rightarrow 'a\ set \Rightarrow bool$ (**infix** ‹$<c$› *50*)
  where $X <c\ C \equiv chain\ C \wedge X \subset C$

A maximal chain is a chain that does not have a superchain.

definition *maxchain* :: $'a\ set \Rightarrow bool$
  where $maxchain\ C \longleftrightarrow chain\ C \wedge (\nexists S.\ C <c\ S)$

We define the successor of a set to be an arbitrary superchain, if such exists, or the set itself, otherwise.

definition *suc* :: $'a\ set \Rightarrow 'a\ set$
  where $suc\ C = (if\ \neg\ chain\ C \vee maxchain\ C\ then\ C\ else\ (SOME\ D.\ C <c\ D))$

lemma *chainI* [*Pure.intro?*]: $C \subseteq A \Longrightarrow (\bigwedge x\ y.\ x \in C \Longrightarrow y \in C \Longrightarrow x \sqsubseteq y \vee y \sqsubseteq x) \Longrightarrow chain\ C$
  unfolding *chain-def* **by** *blast*

lemma *chain-total*: $chain\ C \Longrightarrow x \in C \Longrightarrow y \in C \Longrightarrow x \sqsubseteq y \vee y \sqsubseteq x$
  by (*simp add*: *chain-def*)

lemma *not-chain-suc* [*simp*]: $\neg\ chain\ X \Longrightarrow suc\ X = X$
  by (*simp add*: *suc-def*)

lemma *maxchain-suc* [*simp*]: $maxchain\ X \Longrightarrow suc\ X = X$
  by (*simp add*: *suc-def*)

lemma *suc-subset*: $X \subseteq suc\ X$
  by (*auto simp*: *suc-def maxchain-def intro*: *someI2*)

lemma *chain-empty* [*simp*]: $chain\ \{\}$
  by (*auto simp*: *chain-def*)

lemma *not-maxchain-Some*: $chain\ C \Longrightarrow \neg\ maxchain\ C \Longrightarrow C <c\ (SOME\ D.\ C <c\ D)$
  by (*rule someI-ex*) (*auto simp*: *maxchain-def*)

lemma *suc-not-equals*: $chain\ C \Longrightarrow \neg\ maxchain\ C \Longrightarrow suc\ C \neq C$
  using *not-maxchain-Some* **by** (*auto simp*: *suc-def*)

lemma *subset-suc*:
  assumes $X \subseteq Y$
  shows $X \subseteq suc\ Y$
  using *assms* **by** (*rule subset-trans*) (*rule suc-subset*)

We build a set $\mathcal{C}$ that is closed under applications of *suc* and contains the union of all its subsets.

inductive-set *suc-Union-closed* (‹$\mathcal{C}$›)
  where
    suc: $X \in \mathcal{C} \Longrightarrow suc\ X \in \mathcal{C}$

| *Union* [*unfolded Pow-iff*]: $X \in Pow\ \mathcal{C} \Longrightarrow \bigcup X \in \mathcal{C}$

Since the empty set as well as the set itself is a subset of every set, $\mathcal{C}$ contains at least $\{\} \in \mathcal{C}$ and $\bigcup\ \mathcal{C} \in \mathcal{C}$.

lemma *suc-Union-closed-empty*: $\{\} \in \mathcal{C}$
  and *suc-Union-closed-Union*: $\bigcup \mathcal{C} \in \mathcal{C}$
  using *Union* [*of* {}] **and** *Union* [*of* $\mathcal{C}$] **by** *simp-all*

Thus closure under *suc* will hit a maximal chain eventually, as is shown below.

lemma *suc-Union-closed-induct* [*consumes 1*, *case-names suc Union*, *induct pred*: *suc-Union-closed*]:
  assumes $X \in \mathcal{C}$
    and $\bigwedge X.\ X \in \mathcal{C} \Longrightarrow Q\ X \Longrightarrow Q\ (suc\ X)$
    and $\bigwedge X.\ X \subseteq \mathcal{C} \Longrightarrow \forall x{\in}X.\ Q\ x \Longrightarrow Q\ (\bigcup X)$
  shows $Q\ X$
  using *assms* **by** *induct blast+*

lemma *suc-Union-closed-cases* [*consumes 1*, *case-names suc Union*, *cases pred*: *suc-Union-closed*]:
  assumes $X \in \mathcal{C}$
    and $\bigwedge Y.\ X = suc\ Y \Longrightarrow Y \in \mathcal{C} \Longrightarrow Q$
    and $\bigwedge Y.\ X = \bigcup Y \Longrightarrow Y \subseteq \mathcal{C} \Longrightarrow Q$
  shows Q
  using *assms* **by** *cases simp-all*

27.2 Well-founded induction and recursion adapted to non-strict well-order relations

Here we provide induction and recursion principles specific to *non-strict* well-order relations. Although minor variations of those for well-founded relations, they will be useful for doing away with the tediousness of having to take out the diagonal each time in order to switch to a well-founded relation.

lemma *well-order-induct*:
assumes *IND*: $\bigwedge x.\ \forall y.\ y \neq x \wedge (y, x) \in r \longrightarrow P\ y \Longrightarrow P\ x$
shows *P a*

27.3 The notions of maximum, minimum, supremum, successor and order filter

We define the successor *of a set*, and not of an element (the latter is of course a particular case). Also, we define the maximum *of two elements*, *max2*, and the minimum *of a set*, *minim* – we chose these variants since we consider them the most useful for well-orders. The minimum is defined in terms of the auxiliary relational operator *isMinim*. Then, supremum and successor are defined in terms of minimum as expected. The minimum is only meaningful for non-empty sets, and the successor is only meaningful for sets for which strict upper bounds exist. Order filters for well-orders are also known as "initial segments".

definition *max2* :: $'a \Rightarrow 'a \Rightarrow 'a$

where *max2 a b* ≡ *if* (*a*,*b*) ∈ *r then b else a*

definition *isMinim* :: ′*a set* ⇒ ′*a* ⇒ *bool*
where *isMinim A b* ≡ *b* ∈ *A* ∧ (∀ *a* ∈ *A*. (*b*,*a*) ∈ *r*)

definition *minim* :: ′*a set* ⇒ ′*a*
where *minim A* ≡ *THE b*. *isMinim A b*

definition *supr* :: ′*a set* ⇒ ′*a*
where *supr A* ≡ *minim* (*Above A*)

definition *suc* :: ′*a set* ⇒ ′*a*
where *suc A* ≡ *minim* (*AboveS A*)

28 Well-Order Embeddings as Needed by Bounded Natural Functors

```
theory BNF-Wellorder-Embedding
 imports Hilbert-Choice BNF-Wellorder-Relation
begin
```

In this section, we introduce well-order *embeddings* and *isomorphisms* and prove their basic properties. The notion of embedding is considered from the point of view of the theory of ordinals, and therefore requires the source to be injected as an *initial segment* (i.e., *order filter*) of the target. A main result of this section is the existence of embeddings (in one direction or another) between any two well-orders, having as a consequence the fact that, given any two sets on any two types, one is smaller than (i.e., can be injected into) the other.

28.2 (Well-order) embeddings, strict embeddings, isomorphisms and order-compatible functions

Standardly, a function is an embedding of a well-order in another if it injectively and order-compatibly maps the former into an order filter of the latter. Here we opt for a more succinct definition (operator *embed*), asking that, for any element in the source, the function should be a bijection between the set of strict lower bounds of that element and the set of strict lower bounds of its image. (Later we prove equivalence with the standard definition – lemma *embed-iff-compat-inj-on-ofilter*.) A *strict embedding* (operator *embedS*) is a non-bijective embedding and an isomorphism (operator *iso*) is a bijective embedding.

definition *embed* :: $'a$ *rel* ⇒ $'a'$ *rel* ⇒ ($'a$ ⇒ $'a'$) ⇒ *bool*
where
embed r r' f ≡ ∀ *a* ∈ *Field r*. *bij-betw f* (*under r a*) (*under r'* (*f a*))

lemmas *embed-defs* = *embed-def embed-def*[*abs-def*]

Strict embeddings:

definition *embedS* :: $'a$ *rel* ⇒ $'a'$ *rel* ⇒ ($'a$ ⇒ $'a'$) ⇒ *bool*
where

28.3 Given any two well-orders, one can be embedded in the other

Here is an overview of the proof of of this fact, stated in theorem *wellorders-totally-ordered*:

Fix the well-orders $r::'a$ *rel* and $r'::'a'$ *rel*. Attempt to define an embedding $f::'a \Rightarrow 'a'$ from r to r' in the natural way by well-order recursion ("hoping" that *Field* r turns out to be smaller than *Field* r'), but also record, at the recursive step, in a function $g::'a \Rightarrow$ *bool*, the extra information of whether *Field* r' gets exhausted or not.

If *Field* r' does not get exhausted, then *Field* r is indeed smaller and f is the desired embedding from r to r' (lemma *wellorders-totally-ordered-aux*).

Otherwise, it means that *Field* r' is the smaller one, and the inverse of (the "good" segment of) f is the desired embedding from r' to r (lemma *wellorders-totally-ordered-aux2*).

```

28.4 Uniqueness of embeddings

Here we show a fact complementary to the one from the previous subsection – namely, that between any two well-orders there is *at most* one embedding, and is the one definable by the expected well-order recursive equation. As a consequence, any two embeddings of opposite directions are mutually inverse.

```

29 Constructions on Wellorders as Needed by Bounded Natural Functors

```
theory BNF-Wellorder-Constructions
  imports BNF-Wellorder-Embedding
begin
```

In this section, we study basic constructions on well-orders, such as restriction to a set/order filter, copy via direct images, ordinal-like sum of disjoint well-orders, and bounded square. We also define between well-orders the relations *ordLeq*, of being embedded (abbreviated $\leq o$), *ordLess*, of being strictly embedded (abbreviated $<o$), and *ordIso*, of being isomorphic (abbreviated $=o$). We study the connections between these relations, order filters, and the aforementioned constructions. A main result of this section is that $<o$ is well-founded.

29.4 Ordering the well-orders by existence of embeddings

We define three relations between well-orders:

- *ordLeq*, of being embedded (abbreviated $\leq o$);
- *ordLess*, of being strictly embedded (abbreviated $<o$);
- *ordIso*, of being isomorphic (abbreviated $=o$).

The prefix "ord" and the index "o" in these names stand for "ordinal-like". These relations shall be proved to be inter-connected in a similar fashion as the trio $\leq$, $<$, $=$ associated to a total order on a set.

definition *ordLeq* :: ('*a rel* ∗ '*a*' *rel*) *set*
where
ordLeq = {(*r*,*r*'). *Well-order r* ∧ *Well-order r*' ∧ (∃*f*. *embed r r*' *f*)}

abbreviation *ordLeq2* :: '*a rel* ⇒ '*a*' *rel* ⇒ *bool* (**infix** ‹<=*o*› *50*)
where *r* <=*o r*' ≡ (*r*,*r*') ∈ *ordLeq*

abbreviation *ordLeq3* :: '*a rel* ⇒ '*a*' *rel* ⇒ *bool* (**infix** ‹≤*o*› *50*)
where *r* ≤*o r*' ≡ *r* <=*o r*'

definition *ordLess* :: ('*a rel* ∗ '*a*' *rel*) *set*
where
ordLess = {(*r*,*r*'). *Well-order r* ∧ *Well-order r*' ∧ (∃*f*. *embedS r r*' *f*)}

abbreviation *ordLess2* :: '*a rel* ⇒ '*a*' *rel* ⇒ *bool* (**infix** ‹<*o*› *50*)
where *r* <*o r*' ≡ (*r*,*r*') ∈ *ordLess*

definition *ordIso* :: ('*a rel* ∗ '*a*' *rel*) *set*
where
ordIso = {(*r*,*r*'). *Well-order r* ∧ *Well-order r*' ∧ (∃*f*. *iso r r*' *f*)}

abbreviation *ordIso2* :: '*a rel* ⇒ '*a*' *rel* ⇒ *bool* (**infix** ‹=*o*› *50*)
where *r* =*o r*' ≡ (*r*,*r*') ∈ *ordIso*

lemmas *ordRels-def* = *ordLeq-def ordLess-def ordIso-def*

lemma *ordLeq-Well-order-simp*:
assumes *r* ≤*o r*'
shows *Well-order r* ∧ *Well-order r*'
using *assms* **unfolding** *ordLeq-def* **by** *simp*

Notice that the relations ≤*o*, <*o*, =*o* connect well-orders on potentially *distinct* types. However, some of the lemmas below, including the next one, restrict implicitly the type of these relations to (('*a rel*) ∗ ('*a rel*)) *set* , i.e., to '*a rel rel*.

lemma *ordLeq-reflexive*:
Well-order r ⟹ *r* ≤*o r*
unfolding *ordLeq-def* **using** *id-embed*[*of r*] **by** *blast*

29.5 <o is well-founded

Of course, it only makes sense to state that the <o is well-founded on the restricted type *'a rel rel*. We prove this by first showing that, for any set of well-orders all embedded in a fixed well-order, the function mapping each well-order in the set to an order filter of the fixed well-order is compatible w.r.t. to <o versus *strict inclusion*; and we already know that strict inclusion of order filters is well-founded.

```

29.7 Bounded square

This construction essentially defines, for an order relation *r*, a lexicographic order *bsqr r* on (*Field r*) × (*Field r*), applying the following criteria (in this order):

- compare the maximums;
- compare the first components;
- compare the second components.

The only application of this construction that we are aware of is at proving that the square of an infinite set has the same cardinal as that set. The essential property required there (and which is ensured by this construction) is that any proper order filter of the product order is included in a rectangle, i.e., in a product of proper filters on the original relation (assumed to be a well-order).

30 Cardinal-Order Relations as Needed by Bounded Natural Functors

theory *BNF-Cardinal-Order-Relation*
imports *Zorn BNF-Wellorder-Constructions*
begin

In this section, we define cardinal-order relations to be minim well-orders on their field. Then we define the cardinal of a set to be *some* cardinal-order relation on that set, which will be unique up to order isomorphism. Then we study the connection between cardinals and:

- standard set-theoretic constructions: products, sums, unions, lists, powersets, set-of finite sets operator;
- finiteness and infiniteness (in particular, with the numeric cardinal operator for finite sets, *card*, from the theory *Finite-Sets.thy*).

On the way, we define the canonical ω cardinal and finite cardinals. We also define (again, up to order isomorphism) the successor of a cardinal, and show that any cardinal admits a successor.

Main results of this section are the existence of cardinal relations and the facts that, in the presence of infiniteness, most of the standard set-theoretic constructions (except for the powerset) *do not increase cardinality*. In particular, e.g., the set of words/lists over any infinite set has the same cardinality (hence, is in bijection) with that set.

30.1 Cardinal orders

A cardinal order in our setting shall be a well-order *minim* w.r.t. the order-embedding relation, $\leq o$ (which is the same as being *minimal* w.r.t. the strict order-embedding relation, $<o$), among all the well-orders on its field.

definition *card-order-on* :: *'a set* ⇒ *'a rel* ⇒ *bool*
  where
    card-order-on A r ≡ *well-order-on A r* ∧ (∀ *r'*. *well-order-on A r'* ⟶ *r* ≤*o r'*)

abbreviation *Card-order r* ≡ *card-order-on* (*Field r*) *r*
abbreviation *card-order r* ≡ *card-order-on UNIV r*

  card-order-on A r ⟹ *A* = *Field r* ∧ *Card-order r*
  unfolding *card-order-on-def* **using** *well-order-on-Field* **by** *blast*

The existence of a cardinal relation on any given set (which will mean that any set has a cardinal) follows from two facts:

- Zermelo's theorem (proved in *Zorn.thy* as theorem *well-order-on*), which states that on any given set there exists a well-order;
- The well-founded-ness of $<o$, ensuring that then there exists a minimal such well-order, i.e., a cardinal order.

30.4 Cardinals versus set operations involving infinite sets

Here we show that, for infinite sets, most set-theoretic constructions do not increase the cardinality. The cornerstone for this is theorem *Card-order-Times-same-infinite*, which states that self-product does not increase cardinality – the proof of this fact adapts a standard set-theoretic argument, as presented, e.g., in the proof of theorem 1.5.11 at page 47 in [4]. Then everything else follows fairly easily.

lemma *infinite-iff-card-of-nat*:
¬ *finite A* ⟷ (|*UNIV*::*nat set*| ≤*o* |*A*|)
unfolding *infinite-iff-countable-subset card-of-ordLeq* **..**

The next two results correspond to the ZF fact that all infinite cardinals are limit ordinals:

30.6 The successor of a cardinal

First we define *isCardSuc r r′*, the notion of r' being a successor cardinal of r. Although the definition does not require r to be a cardinal, only this case will be meaningful.

definition *isCardSuc* :: $'a\ rel \Rightarrow 'a\ set\ rel \Rightarrow bool$
where
$isCardSuc\ r\ r' \equiv$
$Card\text{-}order\ r' \wedge r <o\ r' \wedge$
$(\forall (r''::'a\ set\ rel).\ Card\text{-}order\ r'' \wedge r <o\ r'' \longrightarrow r' \leq o\ r'')$

Now we introduce the cardinal-successor operator *cardSuc*, by picking *some* cardinal-order relation fulfilling *isCardSuc*. Again, the picked item shall be proved unique up to order-isomorphism.

definition *cardSuc* :: $'a\ rel \Rightarrow 'a\ set\ rel$
where $cardSuc\ r \equiv SOME\ r'.\ isCardSuc\ r\ r'$

lemma *exists-minim-Card-order*:
$[\![R \neq \{\}; \forall r \in R.\ Card\text{-}order\ r]\!] \Longrightarrow \exists r \in R.\ \forall r' \in R.\ r \leq o\ r'$
unfolding *card-order-on-def* **using** *exists-minim-Well-order* **by** *blast*

lemma *exists-isCardSuc*:
assumes *Card-order r*
shows $\exists r'.\ isCardSuc\ r\ r'$

proof −
  let *?R* = {(*r*′::′*a set rel*). *Card-order r*′ ∧ *r* <*o r*′}
  have |*Pow*(*Field r*)| ∈ *?R* ∧ (∀ *r* ∈ *?R*. *Card-order r*) **using** *assms*
    by (*simp add*: *card-of-Card-order Card-order-Pow*)
  then obtain *r* **where** *r* ∈ *?R* ∧ (∀ *r*′ ∈ *?R*. *r* ≤*o r*′)
    using *exists-minim-Card-order*[*of ?R*] **by** *blast*
  thus *?thesis* **unfolding** *isCardSuc-def* **by** *auto*
qed

lemma *cardSuc-isCardSuc*:
  assumes *Card-order r*
  shows *isCardSuc r* (*cardSuc r*)
  unfolding *cardSuc-def* **using** *assms*
  by (*simp add*: *exists-isCardSuc someI-ex*)

lemma *cardSuc-Card-order*:
  Card-order r ⟹ *Card-order*(*cardSuc r*)
  using *cardSuc-isCardSuc* **unfolding** *isCardSuc-def* **by** *blast*

lemma *cardSuc-greater*:
  Card-order r ⟹ *r* <*o cardSuc r*
  using *cardSuc-isCardSuc* **unfolding** *isCardSuc-def* **by** *blast*

lemma *cardSuc-ordLeq*:
  Card-order r ⟹ *r* ≤*o cardSuc r*
  using *cardSuc-greater ordLeq-iff-ordLess-or-ordIso* **by** *blast*

The minimality property of *cardSuc* originally present in its definition is local to the type ′*a set rel*, i.e., that of *cardSuc r*:

lemma *cardSuc-least-aux*:
  ⟦*Card-order* (*r*::′*a rel*); *Card-order* (*r*′::′*a set rel*); *r* <*o r*′⟧ ⟹ *cardSuc r* ≤*o r*′
  using *cardSuc-isCardSuc* **unfolding** *isCardSuc-def* **by** *blast*

But from this we can infer general minimality:

lemma *cardSuc-least*:
  assumes *CARD*: *Card-order r* **and** *CARD*′: *Card-order r*′ **and** *LESS*: *r* <*o r*′
  shows *cardSuc r* ≤*o r*′
proof −
  let *?p* = *cardSuc r*

lemma *fChoice-iff-Ex*: *P* (*fChoice P*) ⟷ *HOL.Ex P*
  unfolding *fChoice-def*
  by (*fact some-eq-ex*)

We use the *Ex* constant on the right-hand side of *fChoice-iff-Ex* because we want to use the TPTP-native version if fChoice is introduced in a logic that supports FOOL. In logics that don't support it, it gets replaced by fEx during processing. Notice that we cannot use $\exists x.\ P\ x$, as existentials are not skolimized by the metis proof method but *Ex P* is eta-expanded if FOOL is supported.

The *eq-numeral-iff-iszero* lemmas are not declared [*simp*] by default, because for rings of characteristic zero, better simp rules are possible. For a type like integers mod *n*, type-instantiated versions of these rules should be added to the simplifier, along with a type-specific rule for deciding propositions of the form *iszero* (*numeral w*).

bh: Maybe it would not be so bad to just declare these as simp rules anyway? I should test whether these rules take precedence over the *ring-char-0* rules in the simplifier.

48.2 Generalized summation over a set

context *comm-monoid-add*
begin

sublocale *sum*: *comm-monoid-set plus 0*
  defines $sum = sum.F$ **and** $sum' = sum.G$ **..**

abbreviation *Sum* (‹$\sum$›)
  where $\sum \equiv sum\ (\lambda x.\ x)$

end

Now: lots of fancy syntax. First, $sum\ (\lambda x.\ e)\ A$ is written $\sum x{\in}A.\ e$.

syntax (*ASCII*)
  -sum :: *pttrn* ⇒ *'a set* ⇒ *'b* ⇒ *'b::comm-monoid-add* (‹(‹*indent=3 notation=*‹*binder SUM*››*SUM* (-/:-)./ -)› [*0*, *51*, *10*] *10*)
syntax
  -sum :: *pttrn* ⇒ *'a set* ⇒ *'b* ⇒ *'b::comm-monoid-add* (‹(‹*indent=2 notation=*‹*binder* $\sum$››$\sum$ (-/∈-)./ -)› [*0*, *51*, *10*] *10*)

syntax-consts
-sum ⇌ *sum*

translations — Beware of argument permutation!
$\sum i{\in}A.\ b$ ⇌ *CONST sum* ($\lambda i.\ b$) *A*

Instead of $\sum x{\in}\{x.\ P\}.\ e$ we introduce the shorter $\sum x|P.\ e$.

syntax (*ASCII*)
-qsum :: *pttrn* ⇒ *bool* ⇒ *'a* ⇒ *'a* (‹(‹indent=3 notation=‹binder SUM Collect››SUM - |/ -./ -)› [0, 0, 10] 10)
syntax
-qsum :: *pttrn* ⇒ *bool* ⇒ *'a* ⇒ *'a* (‹(‹indent=2 notation=‹binder ∑ Collect››∑ - | (-)./ -)› [0, 0, 10] 10)

syntax-consts
-qsum == *sum*
translations
$\sum x|P.\ t$ => *CONST sum* ($\lambda x.\ t$) $\{x.\ P\}$
print-translation ‹
[(***const-syntax*** ‹sum›, *K* (*Collect-binder-tr'* ***syntax-const*** ‹-qsum›))]

54.18 Powers with integer exponents

The following allows writing powers with an integer exponent. While the type signature is very generic, most theorems will assume that the underlying type is a division ring or a field.

The notation 'powi' is inspired by the 'powr' notation for real/complex exponentiation.

definition *power-int* :: *'a* :: {*inverse*, *power*} ⇒ *int* ⇒ *'a* (**infixr** ‹*powi*› *80*) **where**
power-int x n = (*if n ≥ 0 then x ^ nat n else inverse x ^* (*nat* (−*n*)))

lemma *power-int-0-right* [*simp*]: *power-int x 0* = *1*
and *power-int-1-right* [*simp*]:
power-int (*y* :: *'a* :: {*power*, *inverse*, *monoid-mult*}) *1* = *y*
and *power-int-minus1-right* [*simp*]:
power-int (*y* :: *'a* :: {*power*, *inverse*, *monoid-mult*}) (−*1*) = *inverse y*
by (*simp-all add*: *power-int-def*)

lemma *power-int-of-nat* [*simp*]: *power-int x* (*int n*) = *x ^ n*
by (*simp add*: *power-int-def*)

lemma *power-int-numeral* [*simp*]: *power-int x* (*numeral n*) = *x ^ numeral n*

57.6 Generic symbolic computations

The following type class contains everything necessary to formulate a division algorithm in ring structures with numerals, restricted to its positive segments.

class *linordered-euclidean-semiring-division* = *linordered-euclidean-semiring* +
fixes *divmod* :: ‹*num* ⇒ *num* ⇒ ′*a* × ′*a*›

and *divmod-step* :: ‹'a ⇒ 'a × 'a ⇒ 'a × 'a› — These are conceptually definitions but force generated code to be monomorphic wrt. particular instances of this class which yields a significant speedup.
assumes *divmod-def*: ‹*divmod m n* = (*numeral m div numeral n*, *numeral m mod numeral n*)›
and *divmod-step-def* [*simp*]: ‹*divmod-step l* (*q*, *r*) =
(*if euclidean-size l* ≤ *euclidean-size r then* (*2* ∗ *q* + *1*, *r* − *l*)
else (*2* ∗ *q*, *r*))› — This is a formulation of one step (referring to one digit position) in school-method division: compare the dividend at the current digit position with the remainder from previous division steps and evaluate accordingly.
begin

lemma *fst-divmod*:
‹*fst* (*divmod m n*) = *numeral m div numeral n*›
by (*simp add*: *divmod-def*)

lemma *snd-divmod*:
‹*snd* (*divmod m n*) = *numeral m mod numeral n*›
by (*simp add*: *divmod-def*)

Following a formulation of school-method division. If the divisor is smaller than the dividend, terminate. If not, shift the dividend to the right until termination occurs and then reiterate single division steps in the opposite direction.

lemma *divmod-divmod-step*:

61.5 Intervals of natural numbers

61.5.1 The Constant *lessThan*

lemma *lessThan-0* [*simp*]: *lessThan* (*0*::*nat*) = {}
by (*simp add*: *lessThan-def*)

lemma *lessThan-Suc*: *lessThan* (*Suc k*) = *insert k* (*lessThan k*)
by (*simp add*: *lessThan-def less-Suc-eq*, *blast*)

The following proof is convenient in induction proofs where new elements get indices at the beginning. So it is used to transform {..<*Suc n*} to *0* and {..<*n*}.

lemma *zero-notin-Suc-image* [*simp*]: *0* ∉ *Suc* ' *A*
by *auto*

lemma *lessThan-Suc-eq-insert-0*: {..<*Suc n*} = *insert 0* (*Suc* ' {..<*n*})
by (*auto simp*: *image-iff less-Suc-eq-0-disj*)

lemma *lessThan-Suc-atMost*: *lessThan* (*Suc k*) = *atMost k*
by (*simp add*: *lessThan-def atMost-def less-Suc-eq-le*)

lemma *atMost-Suc-eq-insert-0*: {.. *Suc n*} = *insert 0* (*Suc* ' {.. *n*})
unfolding *lessThan-Suc-atMost*[*symmetric*] *lessThan-Suc-eq-insert-0*[*of Suc n*]
..

lemma *UN-lessThan-UNIV*: (⋃ *m*::*nat*. *lessThan m*) = *UNIV*
by *blast*

61.5.2 The Constant *greaterThan*

lemma *greaterThan-0*: *greaterThan 0* = *range Suc*
unfolding *greaterThan-def*
by (*blast dest*: *gr0-conv-Suc* [*THEN iffD1*])

lemma *greaterThan-Suc*: *greaterThan* (*Suc k*) = *greaterThan k* − {*Suc k*}
unfolding *greaterThan-def*
by (*auto elim*: *linorder-neqE*)

lemma *INT-greaterThan-UNIV*: (⋂ *m*::*nat*. *greaterThan m*) = {}
by *blast*

61.5.3 The Constant *atLeast*

lemma *atLeast-0* [*simp*]: *atLeast* (*0*::*nat*) = *UNIV*
by (*unfold atLeast-def UNIV-def*, *simp*)

lemma *atLeast-Suc*: *atLeast* (*Suc k*) = *atLeast k* − {*k*}
unfolding *atLeast-def* **by** (*auto simp*: *order-le-less Suc-le-eq*)

lemma *atLeast-Suc-greaterThan*: *atLeast* (*Suc k*) = *greaterThan k*
by (*auto simp add*: *greaterThan-def atLeast-def less-Suc-eq-le*)

lemma *UN-atLeast-UNIV*: (⋃ *m*::*nat*. *atLeast m*) = *UNIV*
by *blast*

61.5.4 The Constant *atMost*

lemma *atMost-0* [*simp*]: *atMost* (*0*::*nat*) = {*0*}
by (*simp add*: *atMost-def*)

lemma *atMost-Suc*: *atMost* (*Suc k*) = *insert* (*Suc k*) (*atMost k*)
unfolding *atMost-def* **by** (*auto simp add*: *less-Suc-eq order-le-less*)

lemma *UN-atMost-UNIV*: (⋃ *m*::*nat*. *atMost m*) = *UNIV*
by *blast*

61.5.5 The Constant *atLeastLessThan*

The orientation of the following 2 rules is tricky. The lhs is defined in terms of the rhs. Hence the chosen orientation makes sense in this theory — the reverse orientation complicates proofs (eg nontermination). But outside, when the definition of the lhs is rarely used, the opposite orientation seems preferable because it reduces a specific concept to a more general one.

lemma *atLeast0LessThan* [*code-abbrev*]: $\{0::nat..<n\} = \{..<n\}$
by(*simp add*:*lessThan-def atLeastLessThan-def*)

lemma *atLeast0AtMost* [*code-abbrev*]: $\{0..n::nat\} = \{..n\}$
by(*simp add*:*atMost-def atLeastAtMost-def*)

lemma *lessThan-atLeast0*: $\{..<n\} = \{0::nat..<n\}$
by (*simp add*: *atLeast0LessThan*)

lemma *atMost-atLeast0*: $\{..n\} = \{0::nat..n\}$
by (*simp add*: *atLeast0AtMost*)

lemma *atLeastLessThan0*: $\{m..<0::nat\} = \{\}$
