Hoare Logic for Parallel Programs

Leonor Prensa Nieto

April 19, 2009

Abstract

In the following theories a formalization of the Owicki-Gries and the rely-guarantee methods is presented. These methods are widely used for correctness proofs of parallel imperative programs with shared variables. We define syntax, semantics and proof rules in Isabelle/HOL. The proof rules also provide for programs parameterized in the number of parallel components. Their correctness w.r.t. the semantics is proven. Completeness proofs for both methods are extended to the new case of parameterized programs. (These proofs have not been formalized in Isabelle. They can be found in [1].) Using this formalizations we verify several non-trivial examples for parameterized and non-parameterized programs. For the automatic generation of verification conditions with the Owicki-Gries method we define a tactic based on the proof rules. The most involved examples are the verification of two garbage-collection algorithms, the second one parameterized in the number of mutators.

For excellent descriptions of this work see [2, 4, 1, 3].

Chapter 1

The Owicki-Gries Method

1.1 Abstract Syntax

theory *OG-Com* **imports** *Main* **begin**

Type abbreviations for boolean expressions and assertions:

types
$\quad 'a\ bexp = 'a\ set$
$\quad 'a\ assn = 'a\ set$

The syntax of commands is defined by two mutually recursive datatypes: *'a ann-com* for annotated commands and *'a com* for non-annotated commands.

datatype *'a ann-com* =
$\quad$ *AnnBasic* (*'a assn*) (*'a* ⇒ *'a*)
$\quad$| *AnnSeq* (*'a ann-com*) (*'a ann-com*)
$\quad$| *AnnCond1* (*'a assn*) (*'a bexp*) (*'a ann-com*) (*'a ann-com*)
$\quad$| *AnnCond2* (*'a assn*) (*'a bexp*) (*'a ann-com*)
$\quad$| *AnnWhile* (*'a assn*) (*'a bexp*) (*'a assn*) (*'a ann-com*)
$\quad$| *AnnAwait* (*'a assn*) (*'a bexp*) (*'a com*)
and *'a com* =
$\quad$ *Parallel* (*'a ann-com option* × *'a assn*) *list*
$\quad$| *Basic* (*'a* ⇒ *'a*)
$\quad$| *Seq* (*'a com*) (*'a com*)
$\quad$| *Cond* (*'a bexp*) (*'a com*) (*'a com*)
$\quad$| *While* (*'a bexp*) (*'a assn*) (*'a com*)

The function *pre* extracts the precondition of an annotated command:

consts
$\quad$ *pre* ::*'a ann-com* ⇒ *'a assn*
primrec
$\quad$ *pre* (*AnnBasic r f*) = *r*
$\quad$ *pre* (*AnnSeq c1 c2*) = *pre c1*
$\quad$ *pre* (*AnnCond1 r b c1 c2*) = *r*
$\quad$ *pre* (*AnnCond2 r b c*) = *r*
$\quad$ *pre* (*AnnWhile r b i c*) = *r*

pre (*AnnAwait r b c*) = *r*

Well-formedness predicate for atomic programs:

consts *atom-com* :: *'a com* ⇒ *bool*
primrec
atom-com (*Parallel Ts*) = *False*
atom-com (*Basic f*) = *True*
atom-com (*Seq c1 c2*) = (*atom-com c1* ∧ *atom-com c2*)
atom-com (*Cond b c1 c2*) = (*atom-com c1* ∧ *atom-com c2*)
atom-com (*While b i c*) = *atom-com c*

end

1.2 Operational Semantics

theory *OG-Tran* **imports** *OG-Com* **begin**

types
'a ann-com-op = (*'a ann-com*) *option*
'a ann-triple-op = (*'a ann-com-op* × *'a assn*)

consts *com* :: *'a ann-triple-op* ⇒ *'a ann-com-op*
primrec *com* (*c*, *q*) = *c*

consts *post* :: *'a ann-triple-op* ⇒ *'a assn*
primrec *post* (*c*, *q*) = *q*

constdefs
All-None :: *'a ann-triple-op list* ⇒ *bool*
All-None Ts ≡ ∀ (*c*, *q*) ∈ *set Ts*. *c* = *None*

1.2.1 The Transition Relation

inductive-set
ann-transition :: ((*'a ann-com-op* × *'a*) × (*'a ann-com-op* × *'a*)) *set*
and *transition* :: ((*'a com* × *'a*) × (*'a com* × *'a*)) *set*
and *ann-transition'* :: (*'a ann-com-op* × *'a*) ⇒ (*'a ann-com-op* × *'a*) ⇒ *bool*
(- −*1*→ -[*81*,*81*] *100*)
and *transition'* :: (*'a com* × *'a*) ⇒ (*'a com* × *'a*) ⇒ *bool*

⟫

The following tactic applies *tac* to each conjunct in a subgoal of the form $A \Longrightarrow a1 \wedge a2 \wedge .. \wedge an$ returning n subgoals, one for each conjunct:

ML ⟪
```
fun conjI-Tac tac i st = st |>
      ( (EVERY [rtac conjI i,
          conjI-Tac tac (i+1),
          tac i]) ORELSE (tac i) )
```
⟫

Tactic for the generation of the verification conditions

The tactic basically uses two subtactics:

HoareRuleTac is called at the level of parallel programs, it uses the ParallelTac to solve parallel composition of programs. This verification has two parts, namely, (1) all component programs are correct and (2) they are interference free. *HoareRuleTac* is also called at the level of atomic regions, i.e. ⟨ ⟩ and *AWAIT b THEN - END*, and at each interference freedom test.

AnnHoareRuleTac is for component programs which are annotated programs and so, there are not unknown assertions (no need to use the parameter precond, see NOTE).

NOTE: precond(::bool) informs if the subgoal has the form $\Vert- \ ?p \ c \ q$, in this case we have precond=False and the generated verification condition would have the form $?p \subseteq \ldots$ which can be solved by *rtac subset-refl*, if True we proceed to simplify it using the simplification tactics above.

ML ⟪

```
 fun WlpTac i = (rtac (@{thm SeqRule}) i) THEN (HoareRuleTac false (i+1))

              K all-tac i])
»
```

The final tactic is given the name *oghoare*:

```
ML «
val oghoare-tac = SUBGOAL (fn (-, i) =>
  (HoareRuleTac true i))
»
```

Notice that the tactic for parallel programs *oghoare-tac* is initially invoked with the value *true* for the parameter *precond*.

Parts of the tactic can be also individually used to generate the verification conditions for annotated sequential programs and to generate verification conditions out of interference freedom tests:

```
ML « val annhoare-tac = SUBGOAL (fn (-, i) =>
 (AnnHoareRuleTac i))

val interfree-aux-tac = SUBGOAL (fn (-, i) =>
  (interfree-aux-Tac i))
»
```

The so defined ML tactics are then “exported” to be used in Isabelle proofs.

```
method-setup oghoare = «
 Scan.succeed (K (SIMPLE-METHOD' oghoare-tac)) »
 verification condition generator for the oghoare logic

method-setup annhoare = «
 Scan.succeed (K (SIMPLE-METHOD' annhoare-tac)) »
 verification condition generator for the ann-hoare logic
```

method-setup *interfree-aux* = ⟪
  Scan.succeed (*K* (*SIMPLE-METHOD′ interfree-aux-tac*)) ⟫
  verification condition generator for interference freedom tests

Tactics useful for dealing with the generated verification conditions:

method-setup *conjI-tac* = ⟪
  Scan.succeed (*K* (*SIMPLE-METHOD′* (*conjI-Tac* (*K all-tac*)))) ⟫
  verification condition generator for interference freedom tests

ML ⟪
fun disjE-Tac tac i st = *st* |>
      ((*EVERY* [*etac disjE i*,
          disjE-Tac tac (*i*+*1*),
          tac i]) *ORELSE* (*tac i*))
⟫

method-setup *disjE-tac* = ⟪
  Scan.succeed (*K* (*SIMPLE-METHOD′* (*disjE-Tac* (*K all-tac*)))) ⟫
  verification condition generator for interference freedom tests

end

Chapter 2

Case Study: Single and Multi-Mutator Garbage Collection Algorithms

2.1 Formalization of the Memory

theory *Graph* **imports** *Main* **begin**

datatype $node = Black \mid White$

types
  $nodes = node\ list$
  $edge\ = nat \times nat$
  $edges = edge\ list$

consts $Roots :: nat\ set$

constdefs
  $Proper\text{-}Roots :: nodes \Rightarrow bool$
  $Proper\text{-}Roots\ M \equiv Roots \neq \{\} \wedge Roots \subseteq \{i.\ i<length\ M\}$

  $Proper\text{-}Edges :: (nodes \times edges) \Rightarrow bool$
  $Proper\text{-}Edges \equiv (\lambda(M,E).\ \forall i<length\ E.\ fst(E!i)<length\ M \wedge snd(E!i)<length\ M)$

  $BtoW :: (edge \times nodes) \Rightarrow bool$
  $BtoW \equiv (\lambda(e,M).\ (M!fst\ e)=Black \wedge (M!snd\ e)\neq Black)$

  $Blacks :: nodes \Rightarrow nat\ set$
  $Blacks\ M \equiv \{i.\ i<length\ M \wedge M!i=Black\}$

  $Reach :: edges \Rightarrow nat\ set$
  $Reach\ E \equiv \{x.\ (\exists path.\ 1<length\ path \wedge path!(length\ path - 1)\in Roots \wedge x=path!0$

$\wedge$ ($\forall\, i{<}length\ path\ -\ 1.$ ($\exists\, j{<}length\ E.\ E!j{=}(path!(i{+}1),\ path!i)$)))
$\vee$ $x{\in}Roots$}

Reach: the set of reachable nodes is the set of Roots together with the nodes reachable from some Root by a path represented by a list of nodes (at least two since we traverse at least one edge), where two consecutive nodes correspond to an edge in E.

2.2 The Single Mutator Case

theory *Gar-Coll* **imports** *Graph OG-Syntax* **begin**

declare *psubsetE* [*rule del*]

Declaration of variables:

record *gar-coll-state* =
M :: *nodes*

E :: *edges*
bc :: *nat set*
obc :: *nat set*
Ma :: *nodes*
ind :: *nat*
k :: *nat*
z :: *bool*

2.2.1 The Mutator

The mutator first redirects an arbitrary edge R from an arbitrary accessible node towards an arbitrary accessible node T. It then colors the new target T black.

We declare the arbitrarily selected node and edge as constants:

consts R :: *nat* T :: *nat*

The following predicate states, given a list of nodes m and a list of edges e, the conditions under which the selected edge R and node T are valid:

constdefs
Mut-init :: *gar-coll-state* ⇒ *bool*
Mut-init ≡ ≪ T ∈ *Reach* ´*E* ∧ R < *length* ´*E* ∧ T < *length* ´*M* ≫

For the mutator we consider two modules, one for each action. An auxiliary variable ´*z* is set to false if the mutator has already redirected an edge but has not yet colored the new target.

constdefs
Redirect-Edge :: *gar-coll-state ann-com*
Redirect-Edge ≡ .{´*Mut-init* ∧ ´*z*}. ⟨´*E*:=´*E*[*R*:=(*fst*(´*E*!*R*), *T*)],, ´*z*:= (¬´*z*)⟩

Color-Target :: *gar-coll-state ann-com*
Color-Target ≡ .{´*Mut-init* ∧ ¬´*z*}. ⟨´*M*:=´*M*[*T*:=*Black*],, ´*z*:= (¬´*z*)⟩

Mutator :: *gar-coll-state ann-com*
Mutator ≡
