6.18.29 Nullhomotopic mappings

A mapping out of a sphere is nullhomotopic iff it extends to the ball. This even works out in the degenerate cases when the radius is ≤ 0, and we also don't need to explicitly assume continuity since it's already implicit in both sides of the equivalence.

```
lemma nullhomotopic_from_lemma:

This function returns the angle of a complex number from its representation in polar coordinates. Due to periodicity, its range is arbitrary. *Arg2pi* follows HOL Light in adopting the interval $[0,2\pi)$. But we have the same periodicity issue with logarithms, and it is usual to adopt the same interval for the complex logarithm and argument functions. Further on down, we shall define both functions for the interval $(-\pi,\pi]$. The present version is provided for compatibility.

6.23 The Gamma Function

theory *Gamma_Function*
  imports
  Equivalence_Lebesgue_Henstock_Integration
  Summation_Tests
  Harmonic_Numbers
  HOL−Library.Nonpos_Ints
  HOL−Library.Periodic_Fun
begin

Several equivalent definitions of the Gamma function and its most important properties. Also contains the definition and some properties of the log-Gamma function and the Digamma function and the other Polygamma functions.

Based on the Gamma function, we also prove the Weierstraß product form of the sin function and, based on this, the solution of the Basel problem (the sum over all *1* / *real* (n^2).

6.23.1 The Euler form and the logarithmic Gamma function

We define the Gamma function by first defining its multiplicative inverse *rGamma*. This is more convenient because *rGamma* is entire, which makes proofs of its properties more convenient because one does not have to watch out for discontinuities. (e.g. *rGamma* fulfils *rGamma z* = *z* ∗ *rGamma* (*z* + *1*) everywhere, whereas the Γ function does not fulfil the analogous equation on the non-positive integers)

We define the Γ function (resp. its reciprocale) in the Euler form. This form has the advantage that it is a relatively simple limit that converges everywhere. The limit at the poles is 0 (due to division by 0). The functional equation *Gamma* (*z* + *1*) = *z* ∗ *Gamma z* follows immediately from the definition.

We now show that the series that defines the Γ function in the Euler form converges and that the function defined by it is continuous on the complex halfspace with positive real part.

We do this by showing that the logarithm of the Euler series is continuous and converges locally uniformly, which means that the log-Gamma function defined by its limit is also continuous.

This will later allow us to lift holomorphicity and continuity from the log-Gamma function to the inverse of the Gamma function, and from that to the Gamma function itself.

definition *ln_Gamma_series* :: (*'a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ *'a*
where
ln_Gamma_series z n = *z* ∗ *ln* (*of_nat n*) − *ln z* − (∑ *k*=*1*..*n*. *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma_series'* :: (*'a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ *'a*
where
ln_Gamma_series' z n =
− *euler_mascheroni*∗*z* − *ln z* + (∑ *k*=*1*..*n*. *z* / *of_nat n* − *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma* :: (*'a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *'a* **where**
ln_Gamma z = *lim* (*ln_Gamma_series z*)

We now show that the log-Gamma series converges locally uniformly for all complex numbers except the non-positive integers. We do this by proving that the series is locally Cauchy.

6.23.7 The uniqueness of the real Gamma function

The following is a proof of the Bohr–Mollerup theorem, which states that any log-convex function G on the positive reals that fulfils $G(1) = 1$ and satisfies the functional equation $G(x + 1) = x\, G(x)$ must be equal to the Gamma function. In principle, if G is a holomorphic complex function, one could then extend this from the positive reals to the entire complex plane (minus the non-positive integers, where the Gamma function is not defined).

6.25 The Volume of an n-Dimensional Ball

```
theory Ball_Volume
  imports Gamma_Function Lebesgue_Integral_Substitution
begin
```

We define the volume of the unit ball in terms of the Gamma function. Note that the dimension need not be an integer; we also allow fractional dimensions, although we do not use this case or prove anything about it for now.

```
definition unit_ball_vol :: real ⇒ real where
  unit_ball_vol n = pi powr (n / 2) / Gamma (n / 2 + 1)
```

```
lemma unit_ball_vol_pos [simp]: n ≥ 0 ⟹ unit_ball_vol n > 0
  by (force simp: unit_ball_vol_def intro: divide_nonneg_pos)

lemma unit_ball_vol_nonneg [simp]: n ≥ 0 ⟹ unit_ball_vol n ≥ 0
  by (simp add: dual_order.strict_implies_order)
```

We first need the value of the following integral, which is at the core of computing the measure of an $n + 1$-dimensional ball in terms of the measure of an n-dimensional one.

```

Isabelle's type system makes it very difficult to do an induction over the dimension of a Euclidean space type, because the type would change in the inductive step. To avoid this problem, we instead formulate the problem in a more concrete way by unfolding the definition of the Euclidean norm.

6.26 Integral Test for Summability

theory *Integral_Test*
imports *Henstock_Kurzweil_Integration*
begin

The integral test for summability. We show here that for a decreasing non-negative function, the infinite sum over that function evaluated at the natural numbers converges iff the corresponding integral converges.

As a useful side result, we also provide some results on the difference between the integral and the partial sum. (This is useful e.g. for the definition of the Euler-Mascheroni constant)

An existence theorem for "improper" integrals. Hake's theorem implies that if the integrals over subintervals have a limit, the integral exists. We only need to assume that the integrals are bounded, and we get absolute integrability, but we also need a (rather weak) bound assumption on the function.

theorem *absolutely_integrable_improper*:
fixes *f* :: *'M*::*euclidean_space* ⇒ *'N*::*euclidean_space*
assumes *int_f*: ⋀*c d*. *cbox c d* ⊆ *box a b* ⟹ *f integrable_on cbox c d*

6.30 Embedding Measure Spaces with a Function

```
theory Embed_Measure
imports Binary_Product_Measure
begin
```

Given a measure space on some carrier set Ω and a function *f*, we can define a push-forward measure on the carrier set $f(\Omega)$ whose σ-algebra is the one generated by mapping f over the original sigma algebra.

This is useful e. g. when f is injective, i. e. it is some kind of "tagging" function. For instance, suppose we have some algebraaic datatype of values with various constructors, including a constructor *RealVal* for real numbers. Then *embed_measure* allows us to lift a measure on real numbers to the appropriate subset of that algebraic datatype.

definition *embed_measure* :: *'a measure* ⇒ (*'a* ⇒ *'b*) ⇒ *'b measure* **where**
  embed_measure M f = *measure_of* (*f* ' *space M*) {*f* ' *A* |*A*. *A* ∈ *sets M*}

6.40 Absolute Retracts, Absolute Neighbourhood Retracts and Euclidean Neighbourhood Retracts

```
theory Retracts
imports
  Brouwer_Fixpoint
  Continuous_Extension
```

begin

Absolute retracts (AR), absolute neighbourhood retracts (ANR) and also Euclidean neighbourhood retracts (ENR). We define AR and ANR by specializing the standard definitions for a set to embedding in spaces of higher dimension.

John Harrison writes: "This turns out to be sufficient (since any set in $\mathbb{R}^n$ can be embedded as a closed subset of a convex subset of $\mathbb{R}^{n+1}$) to derive the usual definitions, but we need to split them into two implications because of the lack of type quantifiers. Then ENR turns out to be equivalent to ANR plus local compactness."

```
definition AR :: 'a::topological_space set ⇒ bool where
AR S ≡ ∀ U. ∀ S'::('a ∗ real) set.
  S homeomorphic S' ∧ closedin (top_of_set U) S' ⟶ S' retract_of U

definition ANR :: 'a::topological_space set ⇒ bool where
ANR S ≡ ∀ U. ∀ S'::('a ∗ real) set.
  S homeomorphic S' ∧ closedin (top_of_set U) S'
  ⟶ (∃ T. openin (top_of_set U) T ∧ S' retract_of T)

definition ENR :: 'a::topological_space set ⇒ bool where
ENR S ≡ ∃ U. open U ∧ S retract_of U
```

First, show that we do indeed get the "usual" properties of ARs and ANRs.

6.40.8 The complement of a set and path-connectedness

Complement in dimension N ¿ 1 of set homeomorphic to any interval in any dimension is (path-)connected. This naively generalizes the argument in Ryuji Maehara's paper "The Jordan curve theorem via the Brouwer fixed point theorem", American Mathematical Monthly 1984.

6.47.1 Local Lipschitz continuity

Given a function defined on a real interval, it is Lipschitz-continuous if and only if it is locally so, as proved in the following lemmas. It is useful especially for piecewise-defined functions: if each piece is Lipschitz, then so is the whole function. The same goes for functions defined on geodesic spaces, or more generally on geodesic subsets in a metric space (for instance convex subsets in a real vector space), and this follows readily from the real case, but we will not prove it explicitly.

We give several variations around this statement. This is essentially a connectedness argument.

We deduce that if a function is Lipschitz on finitely many closed sets on the real line, then it is Lipschitz on any interval contained in their union. The difficulty in the proof is to show that any point *z* in this interval (except the maximum) has a point arbitrarily close to it on its right which is contained in a common initial closed set. Otherwise, we show that there is a small interval (*z*, *T*) which does not intersect any of the initial closed sets, a contradiction.

6.49 Convergence of Formal Power Series

```
theory FPS_Convergence
imports
  Generalised_Binomial_Theorem
  HOL−Computational_Algebra.Formal_Power_Series
begin
```

In this theory, we will connect formal power series (which are algebraic objects) with analytic functions. This will become more important in complex analysis, and indeed some of the less trivial results will only be proven there.

6.49.1 Balls with extended real radius

The following is a variant of *ball* that also allows an infinite radius.

The case of division is more complicated and will therefore not be handled here. Handling division becomes much more easy using complex analysis, and we will do so once that is available.

6.49.5 Power series expansions of analytic functions

This predicate contains the notion that the given formal power series converges in some disc of positive radius around the origin and is equal to the given complex function there.

This relationship is unique in the sense that no complex function can have more than one formal power series to which it expands, and if two holomorphic functions that are holomorphic on a connected open set around the origin and have the same power series expansion, they must be equal on that set.

More concrete statements about the radius of convergence can usually be made, but for many purposes, the statment that the series converges to the function in some neighbourhood of the origin is enough, and that can be shown almost fully automatically in most cases, as there are straightforward introduction rules to show this.

In particular, when one wants to relate the coefficients of the power series to the values of the derivatives of the function at the origin, or if one wants to approximate the coefficients of the series with the singularities of the function, this predicate is enough.

6.53 Metrics on product spaces

theory *Function_Metric*
imports
Function_Topology
Elementary_Metric_Spaces
begin

In general, the product topology is not metrizable, unless the index set is countable. When the index set is countable, essentially any (convergent) combination of the metrics on the factors will do. We use below the simplest one, based on L^1, but L^2 would also work, for instance.

What is not completely trivial is that the distance thus defined induces the same topology as the product topology. This is what we have to prove to show that we have an instance of *metric_space*.

The proofs below would work verbatim for general countable products of metric spaces. However, since distances are only implemented in terms of type classes, we only develop the theory for countable products of the same space.

instantiation *fun* :: (*countable*, *metric_space*) *metric_space*
begin

definition *dist_fun_def*:
dist x y = (∑*n*. (*1*/*2*) ^*n* ∗ *min* (*dist* (*x* (*from_nat n*)) (*y* (*from_nat n*))) *1*)

definition *uniformity_fun_def*:
(*uniformity*::((*'a* ⇒ *'b*) × (*'a* ⇒ *'b*)) *filter*) = (*INF e*∈{*0*<..}. *principal* {(*x*, *y*). *dist* (*x*::(*'a*⇒*'b*)) *y* < *e*})

Except for the first one, the auxiliary lemmas below are only useful when proving the instance: once it is proved, they become trivial consequences of the general theory of metric spaces. It would thus be desirable to hide them once the instance is proved, but I do not know how to do this.

lemma *dist_fun_le_dist_first_terms*:

Finally, we show that the topology generated by the distance and the product topology coincide. This is essentially contained in Lemma *fun_open_ball_aux*, except that the condition to prove is expressed with filters. To deal with this, we copy some mumbo jumbo from Lemma *eventually_uniformity_metric* in `~~/src/HOL/Real_Vector_Spaces.thy`

fix *U*::(*'a* ⇒ *'b*) *set*
have *eventually P uniformity* ⟷ (∃ *e*>*0*. ∀ *x* (*y*::(*'a* ⇒ *'b*)). *dist x y* < *e* ⟶ *P* (*x*, *y*)) **for** *P*
unfolding *uniformity_fun_def* **apply** (*subst eventually_INF_base*)
by (*auto simp*: *eventually_principal subset_eq intro*: *bexI*[*of _ min _ _*])
then show *open U* = (∀ *x*∈*U*. ∀$_F$ (*x'*, *y*) *in uniformity*. *x'* = *x* ⟶ *y* ∈ *U*)

```
  unfolding fun_open_ball_aux by simp
qed (simp add: uniformity_fun_def)

end
```

Nice properties of spaces are preserved under countable products. In addition to first countability, second countability and metrizability, as we have seen above, completeness is also preserved, and therefore being Polish.
