6.1 Sigma Algebra

Sigma algebras are an elementary concept in measure theory. To measure — that is to integrate — functions, we first have to measure sets. Unfortunately, when dealing with a large universe, it is often not possible to consistently assign a measure to every subset. Therefore it is necessary to define the set of measurable subsets of the universe. A sigma algebra is such a set that has three very natural and desirable properties.

6.1.1 Families of sets

locale *subset_class* =
  fixes Ω :: *'a set* **and** M :: *'a set set*
  assumes *space_closed*: $M \subseteq Pow\ \Omega$

6.8.3 Measurability

There are two natural sigma-algebras on a product space: the borel sigma algebra, generated by open sets in the product, and the product sigma algebra, countably generated by products of measurable sets along finitely many coordinates. The second one is defined and studied in `Finite_Product_Measure.thy`.

These sigma-algebra share a lot of natural properties (measurability of coordinates, for instance), but there is a fundamental difference: open sets are generated by arbitrary unions, not only countable ones, so typically many open sets will not be measurable with respect to the product sigma algebra (while all sets in the product sigma algebra are borel). The two sigma algebras coincide only when everything is countable (i.e., the product is countable, and the borel sigma algebra in the factor is countably generated).

In this paragraph, we develop basic measurability properties for the borel sigma algebra, and compare it with the product sigma algebra as explained above.

```
lemma measurable_product_coordinates [measurable (raw)]:
  (λx. x i) ∈ measurable borel borel
by (rule borel_measurable_continuous_onI[OF continuous_on_product_coordinates])

lemma measurable_product_then_coordinatewise:
  fixes f::'a ⇒ 'b ⇒ ('c::topological_space)
  assumes [measurable]: f ∈ borel_measurable M
  shows (λx. f x i) ∈ borel_measurable M
proof –
  have (λx. f x i) = (λy. y i) o f
    unfolding comp_def by auto
  then show ?thesis by simp
qed
```

To compare the Borel sigma algebra with the product sigma algebra, we give a presentation of the product sigma algebra that is more similar to the one we used above for the product topology.

```

assumes *integrable* M f *integrable* M g $\bigwedge x.\ x \in space\ M \Longrightarrow |f\ x| \leq g\ x$
shows $|\int x.\ f\ x\ \partial M| \leq (\int x.\ g\ x\ \partial M)$
by (*metis integral_norm_bound_integral assms real_norm_def*)

The next two statements are useful to bound Lebesgue integrals, as they avoid one integrability assumption. The price to pay is that the upper function has to be nonnegative, but this is often true and easy to check in computations.

The next lemma shows that L^1 convergence of a sequence of functions follows from almost everywhere convergence and the weaker condition of the convergence of the integrated norms (or even just the nontrivial inequality about them). Useful in a lot of contexts! This statement (or its variations) are known as Scheffe lemma.

The formalization is more painful as one should jump back and forth between reals and ereals and justify all the time positivity or integrability (thankfully, measurability is handled more or less automatically).

6.17.1 Abstract

The following document presents a proof that the Continuum is uncountable. It is formalised in the Isabelle/Isar theorem proving system.

Theorem: The Continuum $\mathbb{R}$ is not denumerable. In other words, there does not exist a function $f: \mathbb{N} \Rightarrow \mathbb{R}$ such that f is surjective.

Outline: An elegant informal proof of this result uses Cantor's Diagonalisation argument. The proof presented here is not this one.

First we formalise some properties of closed intervals, then we prove the Nested Interval Property. This property relies on the completeness of the Real numbers and is the foundation for our argument. Informally it states that an intersection of countable closed intervals (where each successive interval is a subset of the last) is non-empty. We then assume a surjective function $f: \mathbb{N} \Rightarrow \mathbb{R}$ exists and find a real x such that x is not in the range of f by generating a sequence of closed intervals then using the Nested Interval Property.

theorem *real_non_denum*: $\nexists f :: nat \Rightarrow real.\ surj\ f$
proof
  assume $\exists f::nat \Rightarrow real.\ surj\ f$
  then obtain $f :: nat \Rightarrow real$ **where** *surj f* **..**

First we construct a sequence of nested intervals, ignoring *range f*.

  have $a < b \Longrightarrow \exists\, ka\ kb.\ ka < kb \wedge \{ka..kb\} \subseteq \{a..b\} \wedge c \notin \{ka..kb\}$ **for** $a\ b\ c$ :: *real*

by (*auto simp add*: *not_le cong*: *conj_cong*)
(*metis dense le_less_linear less_linear less_trans order_refl*)
then obtain *i j* **where** *ij*:
$a < b \Longrightarrow i\ a\ b\ c < j\ a\ b\ c$
$a < b \Longrightarrow \{i\ a\ b\ c\ ..\ j\ a\ b\ c\} \subseteq \{a\ ..\ b\}$
$a < b \Longrightarrow c \notin \{i\ a\ b\ c\ ..\ j\ a\ b\ c\}$
for *a b c* :: *real*
by *metis*

define *ivl* **where** *ivl* =
rec_nat (*f 0* + *1*, *f 0* + *2*) (λ*n x*. (*i* (*fst x*) (*snd x*) (*f n*), *j* (*fst x*) (*snd x*) (*f n*)))
define *I* **where** *I n* = {*fst* (*ivl n*) .. *snd* (*ivl n*)} **for** *n*

have *ivl* [*simp*]:
ivl 0 = (*f 0* + *1*, *f 0* + *2*)

6.18.24 Contractible spaces

The definition (which agrees with "contractible" on subsets of Euclidean space) is a little cryptic because we don't in fact assume that the constant "a" is in the space. This forces the convention that the empty space / set is contractible, avoiding some special cases.

definition *contractible_space* **where**
contractible_space X ≡ ∃ *a*. *homotopic_with* (λ*x*. *True*) *X X id* (λ*x*. *a*)
