2.2.22 The topology generated by some (open) subsets

In the definition below of a generated topology, the *Empty* case is not necessary, as it follows from *UN* taking for *K* the empty set. However, it is convenient to have, and is never a problem in proofs, so I prefer to write it down explicitly.

We do not require *UNIV* to be an open set, as this will not be the case in applications. (We are thinking of a topology on a subset of *UNIV*, the remaining part of *UNIV* being irrelevant.)

```
inductive generate_topology_on for S where
```

```
  Empty: generate_topology_on S {}
| Int: generate_topology_on S a ⟹ generate_topology_on S b ⟹ generate_topology_on
S (a ∩ b)
| UN: (⋀k. k ∈ K ⟹ generate_topology_on S k) ⟹ generate_topology_on S (⋃K)
| Basis: s ∈ S ⟹ generate_topology_on S s

lemma istopology_generate_topology_on:
  istopology (generate_topology_on S)
unfolding istopology_def by (auto intro: generate_topology_on.intros)
```

The basic property of the topology generated by a set S is that it is the smallest topology containing all the elements of S:

```
lemma generate_topology_on_coarsest:
  assumes T: istopology T ⋀s. s ∈ S ⟹ T s
        and gen: generate_topology_on S s0

2.2.24 Pullback topology

Pulling back a topology by map gives again a topology. *subtopology* is a special case of this notion, pulling back by the identity. We introduce the general notion as we will need it to define the strong operator topology on the space of continuous linear operators, by pulling back the product topology on the space of all functions.

pullback_topology A f T is the pullback of the topology *T* by the map *f* on the set A.

```

Continuity of addition

The next few lemmas remove an unnecessary assumption in *tendsto_add_ereal*, culminating in *tendsto_add_ereal_general* which essentially says that the addition is continuous on ereal times ereal, except at $(-\infty, \infty)$ and $(\infty, -\infty)$. It is much more convenient in many situations, see for instance the proof of *tendsto_sum_ereal* below.

lemma *tendsto_add_ereal_PInf*:
fixes *y* :: *ereal*
assumes *y*: $y \neq -\infty$
assumes *f*: $(f \longrightarrow \infty)$ *F* **and** *g*: $(g \longrightarrow y)$ *F*
shows $((\lambda x.\ f\ x + g\ x) \longrightarrow \infty)$ *F*
proof −

4.6.2 Radius of convergence

The radius of convergence of a power series. This value always exists, ranges from *0* to ∞, and the power series is guaranteed to converge for all inputs with a norm that is smaller than that radius and to diverge for all inputs with a norm that is greater.

definition *conv_radius* :: (*nat* ⇒ ′*a* :: *banach*) ⇒ *ereal* **where**

conv_radius f = inverse (limsup (λn. ereal (root n (norm (f n)))))

4.8 Function Topology

We want to define the general product topology.

The product topology on a product of topological spaces is generated by the sets which are products of open sets along finitely many coordinates, and the whole space along the other coordinates. This is the coarsest topology for which the projection to each factor is continuous.

To form a product of objects in Isabelle/HOL, all these objects should be subsets of a common type 'a. The product is then Pi_E *I X*, the set of elements from $'i$ to $'a$ such that the *i*-th coordinate belongs to *X i* for all *i* ∈ *I*.

Hence, to form a product of topological spaces, all these spaces should be subsets of a common type. This means that type classes can not be used to define such a product if one wants to take the product of different topological spaces (as the type 'a can only be given one structure of topological space using type classes). On the other hand, one can define different topologies (as introduced in *thy*) on one type, and these topologies do not need to share the same maximal open set. Hence, one can form a product of topologies in this sense, and this works well. The big caveat is that it does not interact well with the main body of topology in Isabelle/HOL defined in terms of type classes... For instance, continuity of maps is not defined in this setting.

As the product of different topological spaces is very important in several areas of mathematics (for instance adeles), I introduce below the product topology in terms of topologies, and reformulate afterwards the consequences in terms of type classes (which are of course very handy for applications).

Given this limitation, it looks to me that it would be very beneficial to revamp the theory of topological spaces in Isabelle/HOL in terms of topologies, and keep the statements involving type classes as consequences of more general statements in terms of topologies (but I am probably too naive here).

Here is an example of a reformulation using topologies. Let

$continuous\_map\ T1\ T2\ f =$
  $((\forall\ U.\ openin\ T2\ U \longrightarrow openin\ T1\ (f-`U \cap topspace(T1)))$
    $\wedge\ (f`(topspace\ T1) \subseteq (topspace\ T2)))$

be the natural continuity definition of a map from the topology *T1* to the topology *T2*. Then the current *continuous_on* (with type classes) can be redefined as

$continuous\_on\ s\ f =$
  $continuous\_map\ (top\_of\_set\ s)\ (topology\ euclidean)\ f$

In fact, I need *continuous_map* to express the continuity of the projection on subfactors for the product topology, in Lemma *continuous_on_restrict_product_topology*, and I show the above equivalence in Lemma *continuous_map_iff_continuous*.

I only develop the basics of the product topology in this theory. The most important missing piece is Tychonov theorem, stating that a product of compact spaces is always compact for the product topology, even when the product is not finite (or even countable).

I realized afterwards that this theory has a lot in common with `~~/src/HOL/Library/Finite_Map.thy`.

4.8.1 The product topology

We can now define the product topology, as generated by the sets which are products of open sets along finitely many coordinates, and the whole space along the other coordinates. Equivalently, it is generated by sets which are one open set along one single coordinate, and the whole space along other coordinates. In fact, this is only equivalent for nonempty products, but for the empty product the first formulation is better (the second one gives an empty product space, while an empty product should have exactly one point, equal to *undefined* along all coordinates.

So, we use the first formulation, which moreover seems to give rise to more straightforward proofs.

definition $product\_topology::('i \Rightarrow ('a\ topology)) \Rightarrow ('i\ set) \Rightarrow (('i \Rightarrow 'a)\ topology)$
  where $product\_topology\ T\ I =$
    $topology\_generated\_by\ \{(\Pi_E\ i{\in}I.\ X\ i)\ |X.\ (\forall i.\ openin\ (T\ i)\ (X\ i)) \wedge finite\ \{i.\ X\ i \neq topspace\ (T\ i)\}\}$

abbreviation $powertop\_real :: 'a\ set \Rightarrow ('a \Rightarrow real)\ topology$
  where $powertop\_real \equiv product\_topology\ (\lambda i.\ euclideanreal)$

The total set of the product topology is the product of the total sets along each coordinate.

proposition *product_topology*:
  $product\_topology\ X\ I =$

4.9.7 The strong operator topology on continuous linear operators

Let '*a* and '*b* be two normed real vector spaces. Then the space of linear continuous operators from '*a* to '*b* has a canonical norm, and therefore a canonical corresponding topology (the type classes instantiation are given in `Bounded_Linear_Function.thy`).

However, there is another topology on this space, the strong operator topology, where T_n tends to T iff, for all x in '*a*, then $T_n\ x$ tends to $T\ x$. This is precisely the product topology where the target space is endowed with the norm topology. It is especially useful when '*b* is the set of real numbers, since then this topology is compact.

We can not implement it using type classes as there is already a topology, but at least we can define it as a topology.

Note that there is yet another (common and useful) topology on operator spaces, the weak operator topology, defined analogously using the product topology, but where the target space is given the weak-* topology, i.e., the pullback of the weak topology on the bidual of the space under the canonical embedding of a space into its bidual. We do not define it there, although it could also be defined analogously.

apply (*rule continuous_on_inv*)

```
  apply (simp_all add: assms *)
  done
qed
```

Invertible derivative continuous at a point implies local injectivity. It's only for this we need continuity of the derivative, except of course if we want the fact that the inverse derivative is also continuous. So if we know for some other reason that the inverse function exists, it's OK.

4.10.23 The concept of continuously differentiable

John Harrison writes as follows:

"The usual assumption in complex analysis texts is that a path γ should be piecewise continuously differentiable, which ensures that the path integral exists at least for any continuous f, since all piecewise continuous functions are integrable. However, our notion of validity is weaker, just piecewise differentiability. . . [namely] continuity plus differentiability except on a finite set. . . [Our] underlying theory of integration is the Kurzweil-Henstock theory. In contrast to the Riemann or Lebesgue theory (but in common with a simple notion based on antiderivatives), this can integrate all derivatives."

"Formalizing basic complex analysis." From Insight to Proof: Festschrift in Honour of Andrzej Trybulec. Studies in Logic, Grammar and Rhetoric 10.23 (2007): 151-165.

And indeed he does not assume that his derivatives are continuous, but the penalty is unreasonably difficult proofs concerning winding numbers. We need a self-contained and straightforward theorem asserting that all derivatives can be integrated before we can adopt Harrison's choice.
